This mainly consists in constructing drawing and other rollers by the application thereto of woollen cloth, &c., between the outer cylinder or covering of prepared india rubber, and the internal boss or other roller to prevent slipping of the india-rubber covering thereon. *Patent completed.*

251. E. T. HUGHES. "Improvements in the manufacture of biscuits." (A communication.) Dated Jan. 27, 1859.

Here gluten is mixed with wheat flour, and then mixed with oil, butter, &c., in certain portions. *Patent completed.*

252. G. F. BRADBURY and J. J. KING. "Improvements in certain apparatus applicable to sewing machines." Dated Jan. 27, 1859.

This relates to the binding guide, and consists in forming it of an internal block surrounded by an external case, having a space between them through which the binding passes until it arrives at the end of the block, when it is drawn at or near right angles to the space through a curved groove at the end or side of the block of the desired form and size of the exterior of the binding, leaving the interior free to cover the article to be bound and held close to it until the stitch is made. *Patent completed.*

253. W. CROWTHER. "Improvements in the manufacture of prussiates of potash or soda, and in recovering a useful material therefrom." Dated Jan. 27, 1859.

Here the horn, wood, or other substance is first treated with a hot solution of potash or soda by which it is dissolved. This liquid is then evaporated to dryness; after which the product is placed in the usual pot and submitted to the required temperature for fusion. By the same process prussiates of potash are manufactured from woollen and other materials. *Patent completed.*

254. J. GATHERCOLE. "Improved machinery for manufacturing envelopes and paper bags." Dated Jan. 27, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

255. I. ZACHERONI. "An improved method of preventing the escape of smoke into the atmosphere, and in the construction of chimney pots or tops for curing smoking chimneys." Dated Jan. 28, 1859.

This consists in constructing the chimney without an opening at the top in two or more shafts, to allow the smoke to ascend one or more, and descend by the others, which have valves opening one way, so that the smoke cannot return. These downward shafts terminate in large chambers, where the smoke will be deposited as soot, the gases that have not lodged being returned to the furnaces or fires for combustion. The deposit can be used as a fertilizer. *Patent completed.*

256. W. ROBERTSON. "A new apparatus for propelling boats on canals, rivers, and lakes, of moderate depth." Dated Jan. 28, 1859.

This consists in the use of an endless chain or chains passing over pulleys so fixed and arranged upon the boat as to be capable of being supported and moved forwards or backwards by them, and the chain or chains being of such a length that they reach to and lie upon the bottom of the canal, river, or lake to be navigated. *Patent completed.*

257. G. BARTHOLOMEW. "Improvements in shoes for horses and other animals requiring such shoes, and in the means of attaching the same to the feet." Dated January 28, 1859.

Here the shoe may be formed in the ordinary way except that on each side it is separated from that forming the front, and the parts are connected to a steel or other elastic plate by which flexibility between

the fore and hind parts of the under surface of the shoe is attained. These parts of the shoe are attached to an outer frame or wall rising up the hoof, and extending from the front backwards. The shoes are attached to the hoof in a manner similar to that described in the specification of a previous patent, dated Feb. 1, 1858. *Patent abandoned.*

258. C. E. AMOS and J. FRANCIS. "Improvements in water pressure engines, and their application to pumping machinery." Dated Jan. 28, 1859.

This invention is not described apart from the drawings. *Patent completed.*

259. F. PRINCE. "A new breech-loading gun." Dated Jan. 28, 1859.

This consists principally in a new plan for opening and closing the breech-end of fire-arms for inserting the cartridge at the said breech-end; also, in an improved method of priming the arm. *Patent completed.*

260. W. YATES. "Improvements in furnaces." Dated Jan. 28, 1859.

This consists in forming the fire-doors of furnaces in two parts moving on an axis or upon axes, so that one part may be opened more or less to regulate the admission of fuel which is thrown in above it, and the other part to be closed ordinarily, but to be capable of being opened to afford entrance to the interior of the furnace. In this latter part a slide door is placed to admit tools for stoking the fire, &c. Some of the fire-bars are made moveable together, and are worked by hand or by machinery, so as to force the fuel gradually down the bars and to keep it stirred. *Patent abandoned.*

261. R. GRIFFITHS. "Improvements in regulating the pressure of steam in boilers, and in preventing the accumulation of deposit therein." (Partly a communication.) Dated Jan. 28, 1859.

Here, to regulate the pressure of steam in steam-boilers, the steam is caused to act upon apparatus in connection with the damper, so that the apparatus may partially open or close it according as the pressure is less or greater than that which it is wished to maintain. The accumulation of deposit is prevented by a number of balls being placed in the boiler and kept in motion by the action of the water. *Patent abandoned.*

262. H. WATSON. "Improvements in the manufacture of Knotter plates, used in the manufacture of paper." Dated Jan. 28, 1859.

The peculiarity of this invention consists in arranging the circular saw to cut from the reverse or smooth side of the plate. *Patent completed.*

263. A. BARCLAY. "Improvements in obtaining and distributing or applying electricity and magnetism." Dated Jan. 28, 1859.

The specification of this invention is too elaborate to be quoted here at any sufficient length. *Patent abandoned.*

264. L. LEISLER. "Improvements in extracting metallic copper from the pyrites residuum of vitriol works, and from other substances." (A communication.) Dated Jan. 29, 1859.

The patentee takes the pyrites, residuum of the vitriol works from which the whole or the greater part of the sulphur has been turned off, and treats it in suitable vessels with muriatic acid largely diluted with water. *Patent abandoned.*

265. J. LANE. "New or improved machinery for the manufacture of screws, and for tapping nuts for screws." Dated Jan. 29, 1859.

This invention is not described apart from the drawings. *Patent completed.*

266. J. MACKENZIE. "An improved method of operating ventilating valves, especially applicable to ventilating gas-burners." Dated Jan. 29, 1859.

This consists in closing the exit passage of ventilating gas-burners by a valve opened by the pressure of the gas flowing to the burner, and closed upon the pressure being withdrawn or cut off. *Patent completed.*

267. J. MARINO. "An inodorous closet or commode." Dated Jan. 29, 1859.

This invention is not described apart from the drawings. *Patent completed.*

268. G. DAVIES. "Improvements in apparatus applicable to measuring, regulating the pressure of, and consuming gas for illumination." (A communication.) Dated Jan. 29, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

269. H. GRISSELL. "Improvements in machinery for moving ships or vessels on slips or inclined ways." Dated Jan. 29, 1859.

The hydrostatic presses are arranged to act in succession on a chain so as to produce a continuous motion to such chain and to the cradle or carriage connected thereto. *Patent completed.*

270. J. J. A. de BRONAC and A. J. M. DEHERETON

"A new or improved process for treating metallic sulphurets, phosphurets, arseniurets, antimonurets, and particularly sulphuretted ores of lead, antimony, copper, silver, zinc." Dated Jan. 29, 1859.

The principle of this process is based upon the energetic re-action to which spongy iron is subject. The chief advantages resulting are, 1, the suppression of the preliminary roasting. 2. The rapid extraction of the sulphurets at a low temperature from different metals. *Patent completed.*

271. J. MEACHAM. "Improvements in apparatus for clasping and closing books, purses, reticules, and other similar articles, and for retaining and securing paper, documents, letters, bills, and other memoranda." Dated Jan. 29, 1859.

This consists, 1, of an elastic clasp, the sides of which are rigid, but the clasp being elastic allows of the insertion of papers, &c. 2. Of an elastic band for closing books, &c. The band has a rigid loop for receiving the back of the book, and two hooks are fastened to the covers. The band is then secured by a stud and slot, and forms a spring-clasp, so that the book is fastened while it will admit of being opened to receive papers. 3. Of an elastic band with hooks or other similar fastenings. *Patent abandoned.*

272. T. P. SMITH. "An apparatus for guiding or directing the pen or pencil in writing or drawing." Dated Jan. 31, 1859.

The patentee places on the forefinger of the right hand a ring and rest or hook of such shape as to allow the pen shaft or pencil to rest therein. *Patent completed.*

273. D. BENTLEY. "Improvements in self-acting apparatus, applicable to letter-press printing-machines for supplying and removing the paper." Dated Jan. 31, 1859.

This consists in applying to letter-press printing-machines an air cylinder to which suitable jointed or flexible pipes are connected. The air cylinder has a piston, which in moving forms a partial vacuum in the pipes, and this vacuum is made available for lifting the upper sheet of paper from the pile by which the printing machine is supplied, and suitable machinery is employed to bring forward the sheet of paper so lifted. *Patent abandoned.*

274. J. RAYWOOD. "Certain improvements in the construction and method of working sewing machines." Dated Jan 31, 1859.

This invention is not sufficiently described apart from the drawings. *Patent completed.*

275. T. WILSON. "Improvements in breech-loading and other fire-arms." Dated Jan. 31, 1859.

This consists in certain methods of constructing the breech ends and locks of fire-arms in order that a longer and lower spring may be employed than in the ordinary construction, and an easier action obtained. *Patent abandoned.*

276. J. ROBERTSON. "Improvements in details, by which motive force is transmitted in machinery." Dated Jan. 31, 1859.

This invention is not described apart from the drawings. *Patent completed.*

277. H. J. NEWCOMBE. "An improved apparatus for heating or warming buildings." Dated Jan. 31, 1859.

This consists of a furnace of suitable construction, in connection with which are several series of pipes, suitably arranged for heating the various parts of a building. The heat is regulated by dampers. *Patent abandoned.*

278. J. P. BOOTH. "Improvements in ventilating ships." Dated Jan. 31, 1859.

This consists in causing currents of air to pass through vertical or downcast shafts, communicating with horizontal, longitudinal, or transverse shutters having apertures suitably arranged for conveying the air to any desired part of the ship." *Patent completed.*

279. A. V. NEWTON. "An improved method of extracting gold and silver from their ores." (A communication.) Dated Jan. 31, 1859.

Here the ore is first broken fine and sifted, after which chloride of sodium is added and thoroughly incorporated by being passed through a burr-stone mill. This mixture is then placed in a furnace for roasting. The ore is next ground with the admixture of wood ash, and bolted fine. The mass is next placed in the amalgamator, and sufficient water added to cause the mercury to separate into globules and filter through it. Soda ash is next added to cleanse the mercury. To this mass pieces of bar iron are now added to facilitate the trituration. The amalgamator being put in motion, the mercury is then to be applied, and 6lb. shot added to act as triturator. The machine is then again set in motion, and the temperature raised to about 150° Fah: After a time sulphate of iron in solution is added to decompose the chloride of gold, and precipitate it in the metallic

state. The consistency of the mass is next reduced by adding hot water thereto, and the motion of the machine continued until the globules of mercury collect in a body. The mercury is then drawn off, and the residuum washed, after which the mercury may be separated from the gold by any process now known. *Patent abandoned.*

280. J. GRIMOND. "Improvements in the manufacture of hearth rugs." Dated Feb. 1, 1859.

This consists in manufacturing hearth rugs of jute, or jute hemp, with a mixture of cotton, or wool, or other suitable fibre. The patentee weaves the same in a "kiddier" loom. *Patent completed.*

281. L. BIGOLIER. "A new brake for railway carriages." Dated Feb. 1, 1859.

This invention is not described apart from the drawings. *Patent completed.*

282. J. HOSKING and T. COCK. "Improvements in furnaces or fire-places." Dated Feb. 1, 1859.

The object here is to improve the draught, and the invention consists in closing the back of the furnace, where the bridge is ordinarily placed, and in closing the ash-pit, where the draught is usually admitted to the grate. The ordinary fire-door is dispensed with, and the door-way thus becomes the opening for the admission of the draught, which will pass down below the fire-bars to the ordinary flue leading to the chimney: *Patent abandoned.*

283. S. B. EVELEIGH. "An improved form or construction of hats or covering for the head." Dated Feb. 1, 1859.

This relates principally to hats for police officers, and the invention consists in the combination of the peculiar form of the military "chaco," with the ordinary brimmed hat of the civilian. *Patent completed.*

284. R. NEEDHAM. "An improved water-gauge for steam-boilers." Dated Feb. 1, 1859.

This consists, 1, in providing in the gauge very large passages for the water in order that they may not become choked. 2. In the use of a hollow conical plug in the taps or valves of water gauges, so constructed that the water is supplied to the gauge through the hollow plug, and communication made with the boiler and shut off thereby. *Patent completed.*

285. S. PLIMSOLE. "Mining apparatus for use in mining coal and other minerals, and also for separating the small coal and crushed ores from the shale, dirt, and other matters with which it may be in combination, and for drying the same." Dated Feb. 1, 1859.

This consists, 1, in substituting for the pick a circular or segmental saw, centring in a saddle which traverses one, two, or more parallel rods of iron, placed horizontally for undermining, and vertically for the perpendicular cuts required for straight work. 2. In separating the small coal from the shale, &c., by producing the required action of the water by turning the steam into the water below the coal or crushed ore, thereby dispensing with steam engines. The steam pipes are to be coated with white enamel to diminish the radiation of heat. The drying is effected by hot air. *Patent abandoned.*

286. M. A. WALKER and R. WALKER. "Certain improvements in the manufacture of percussion caps, and in the apparatus for effecting certain parts of the same." Dated Feb. 1, 1859.

This consists, 1, in the means of lining and water-proofing percussion caps. 2. In the form of the blank or shells of percussion caps as applied in a particular way for the discharge of fire-arms. 3. In the mechanical arrangements for giving effect to certain parts of the invention. *Patent abandoned.*

287. R. GORMULLY. "Improvements in pianofortes with upright frames." Dated Feb. 1, 1859.

Here the strings are placed diagonally from back bottom to front top, or the reverse, either as a simple diagonal, or as a transverse diagonal. The strings are attached to a loose frame, the upper part or rest plank of which is formed of two pieces, between which the strings are attached to rest, formed so that the pull of the strings is direct. Or the strings are attached to a solid face, thick at the base end, and thin at treble end. The sound board is loose to allow of free vibration. To such backs is applied the action ordinarily only used in the grand horizontal pianofortes, with its checks, dampers, &c., the object being simplicity and strength. The sound board is of glass or paste board. The ends of the instrument are formed of fretwork in wood, metal, gutta-percha, silk, or long cloth. The keys are of crystal, and arranged chromatically. The name board is of crystal. The centre of top rail of top door has a stick for a candle or lamp, so that light may fall direct on the music book beneath. *Patent abandoned.*

288. T. P. PURSGLOVE. "Improvements in barometers." Dated Feb. 1, 1859.

Here the inventor adjusts a chamber on the upper end of the mercurial column, this chamber having a depth of from four to five inches, and with any convenient breadth. From the lower end of this chamber he leads a spiral sig-sag or straight tube. This tube passes down either a portion, or down the whole of the remaining distance of the 31 inches of vertical height, including the chamber and lower portion of the pipe. To the lower part of this tube or column of mercury he attaches a flexible bag which is in communication with the vertical column. This bag does not depend upon the end of the column, but is attached to suitable mechanism so arranged as to indicate the variations of the atmospheric pressure, which will cause a corresponding increase or diminution in the weight of the mercury that is at the lower end. This bag not being rigidly attached to the tube can be accurately adjusted to the mechanism above referred to, and the weight thereof will thereby be indicated. *Patent abandoned.*

289. R. A. BROOMAN. "Improvements in sewing machines." (A communication.) Dated Feb. 1, 1859.

This relates to the employment of a barbed needle, and consists, 1, in a means of actuating the said needle whereby its movements through the material shall also produce the feeding of the same. 2. In a method of regulating the vibration of the said needle whereby the feed for giving the various lengths of stitches is obtained. The invention is not described apart from the drawings. *Patent completed.*

290. G. A. WALLER. "Improvements in the means of, and apparatus for, expressing liquid from semi-fluid substances and other substances containing liquid." Dated Feb. 1, 1859.

This consists in expressing liquid from semi-fluid substances and others containing liquid by the pressure of water or other liquid, or of air, gas, or other fluid forced into a bag or case introduced into a vessel with perforated sides, or with sides formed of bars with apertures between them, or otherwise constructed to allow of the passage of liquid through them. *Patent completed.*

291. M. LOAM. "Improvements in machinery for raising sewage and other waters and matters." Dated Feb. 1, 1859.

This consists in raising the sewage, &c., by means of a wheel having buckets suitably arranged around its inner periphery, and a trough or canal suitably placed to receive the contents of the buckets as the wheel revolves. *Patent completed.*

292. C. CROCKFORD. "A mode or method of producing metallic sulphates." Dated Feb. 1, 1859.

This consists in exposing the oxides of chlorides of copper, iron, zinc, &c., to the action of sulphurous acid gas, or the vapour of water charged with air, whereby they become converted into sulphates. *Patent abandoned.*

293. M. HENRY. "The manufacture and useful applications of certain bituminous products and compounds of bitumen and other matters, and treating and applying certain natural bitumen or bitumens for such purposes." (A communication.) Dated Feb. 1, 1859.

This appears to relate chiefly to the treatment of a bituminous substance found in the West Indies, and known as "chapatote." In the process preferred the bitumen is melted a little at a time in a close furnace boiler, and when sufficiently fluid the heat is reduced so as to allow it to simmer, stirring it from time to time; resin or other oil may be added to it, the temperature raised, and inert substances combined with it in another boiler and furnace, and the compound poured into moulds powdered with clay. *Patent abandoned.*

294. E. H. BENTALL. "Improvements applicable to machinery for grinding or pulverising various substances." Dated Feb. 1, 1859.

This consists in enclosing the grinding apparatus in a chamber, and admitting a blast of air to the bed of the grinding mill, so as to blow away the fine particles directly they are formed. These fine particles are conveyed away from the grinding chamber to another close chamber in which they are allowed to settle, and as the distance they are carried by the blast will depend upon the weight of the particles, it will be evident that by dividing the settling chamber into compartments powders of different degrees of fineness will be obtained. *Patent completed.*

295. W. E. NEWTON. "An improved blowing machine." (A communication.) Dated Feb. 1, 1859.

The object here is to produce a steady, continuous, and uniform blast which is capable of being altered or modified at pleasure. The invention is not described apart from the drawings. *Patent completed.*

296. E. E. ALLEN. "Improvements in stereoscopic apparatuses." Dated Feb. 2, 1859.

These improvements consist in mounting stereoscopic views upon suitable lengths of silk, which are wound upon rollers fixed in cases which collapse, the rollers being operated upon by means of ivory thumb-screws. The stereoscopes are also made collapsible, and are attached to the cases containing the views. When not in use the cases, with a hundred or more views and stereoscope complete, measure only seven inches in length, three inches in width, and two inches in depth. When opened out for the exhibition of the views the cases are extended to a suitable width, the stereoscope being lifted up and adjusted to any sight. *Patent completed.*

297. E. WILKINS. "Improvements in drain pipes and tiles for draining and liquid manuring land." Dated Feb. 2, 1859.

This consists in forming half round drain pipes with scalloped or vandyked openings or spaces along one or both of their longitudinal edges, so that when laid down upon a flat surface with their convex sides uppermost there shall be small spaces or openings for the exit or entrance of liquid, so as to serve either for draining or for distributing liquid to the subsoil of land. *Patent completed.*

298. R. LANCASTER. "An improved mode of ventilating coal and other mines." Dated Feb. 2, 1859.

This consists in supplying heated air to any portion of the upcast shaft, by which means the air is rarefied therein, and the atmospheric air descending the down-cast shaft to fill up the partial vacuum thus formed produces the requisite current of fresh air for ventilating the mine. The air is highly heated by a furnace placed at the mouth of the pit, and forced the requisite distance down the upcast shaft by a blast-engine. *Patent abandoned.*

299. F. F. RATEAU. "An improved steam-engine actuated by regenerated steam." Dated Feb. 2, 1859.

Here the steam is generated at about three atmospheres pressure in a boiler surrounding the fire-box, and on issuing from the boiler is conveyed into a superheating receiver placed within the fire-box. The steam superheated being thus brought almost simultaneously to a very high pressure, rushes from the receiver into the steam chest of a horizontal cylinder, where it is distributed in the usual way by a slide valve; as it escapes therefrom it is conveyed by a pipe to a second cylinder, where it expands and works in the same way; thence the steam is conveyed back to the boiler, which it enters freely after raising a valve, because its pressure is still higher than that of the steam in the boiler. The steam cylinders are in a horizontal position, their rods being in a straight line are keyed, working in suitable guides; the slide has the shape of a frame standing upright, and a special brace, in which a cranked pin or cranked shaft journal revolves, sliding up and down in the slide, so that the main shaft is caused directly to revolve by the two sliding motions without the help of a connecting rod. *Patent abandoned.*

300. J. R. COOPER. "Improvements in breech-loading fire-arms." Dated Feb. 2, 1859.

This consists in certain methods of connecting the barrels of breech-loading fire-arms with the break off of the said fire-arms, by which the charge and discharge may be rapidly effected. *Patent abandoned.*

301. S. TRARNER. "Improvements in ornamenting surfaces." Dated Feb. 2, 1859.

This consists essentially in gilding, silvering, or bronzing the said surfaces on those parts to which the design is to be applied, and in afterwards transferring thereto designs printed upon transfer paper, the said transfer designs concealing certain parts of the gilded, silvered, or bronzed surface. *Patent completed.*

302. J. BUNCHEE. "Improvements in the manufacture of eyes or fastenings for stair rods." Dated Feb. 2, 1859.

This consists in manufacturing the eyes or fastenings of stair rods by piercing or drilling, and bending strips or bands of rolled or drawn sheet metal, or flat or other shaped wire. *Patent completed.*

303. I. CLEMENTS. "A new or improved method of manufacturing curtain rings." Dated Feb. 2, 1859.

This consists in manufacturing curtain rings by first cutting rings from sheet metal, and afterwards shaping the rings by suitable dies. *Patent completed.*

304. J. HIRST, jun., and J. HOLLINGWORTH. "Improvements in the construction of power looms." Dated Feb. 2, 1859.

This relates, 1, when a series of lifting shuttle boxes is used to operating them by a series of cams or tappets capable of being slid so as to bring the particular cam or tappet into position to operate upon the connecting means to the boxes in order to insure the box required being brought into a line with the race or lay, and at the same time operating supporting catches to such boxes to release them to the extent desired to enable the particular catches

alone to come into position to support the particular box. The sliding of the tappets is effected by an L-lever, or L-levers operated by chains of pattern surfaces; and such L-levers are held between the changes of surfaces by catches or otherwise. 2. To clearing the web when a series of rising boxes is used. For this purpose the front part of the lay is cut away, the filbow is attached to the end of the lay, and the lay sword and the shuttle-boxes at the part adjoining the lay, as is also the lay, are bevelled to admit of the web falling down out of the way of the upper shuttles. *Patent completed.*

305. G. LEACH. "Improvements in leasing yarn or thread in the hank, and in machinery for winding off the same." Dated Feb. 2, 1859.

This relates, 1, to a mode of dividing the hank into given portions, and preserving such divided portions so that the thread or yarn may be correctly placed upon the swift or holding apparatus for being wound off. 2. To a novel machine for holding the yarn, &c., while being wound from the hank. *Patent completed.*

306. H. F. KEMP and W. SKRY. "An improved food for cattle." Dated Feb. 2, 1859.

This relates to the manufacture of food for cattle to be used either in the form of cake or meal, from beet and other such like roots after distillation, maceration, or expression, either separately or combined with other substances. *Patent abandoned.*

307. T. STORER. "A new or improved funeral carriage." Dated Feb. 3, 1859.

This consists of a carriage the body of which is divided by a transverse division into two compartments, entrance to one of the said compartments being by doors at the sides of the carriage, and to the other by a door at the back of the carriage, the receptacle for the coffin being situated under the floor of the carriage. *Patent completed.*

308. J. WOODROW. "Improvements in the manufacture of hats or coverings for the head." Dated Feb. 3, 1859.

This consists in the use of a woven fabric called "Swiss tissue," as an external covering for the foundation or body of summer hats. *Patent abandoned.*

309. W. CLAYTON and J. GOODFELLOW. "Certain improvements in metallic pistons." Dated Feb. 3, 1859.

This relates to what is known as Goodfellow's patent piston, and consists in the use of a fourth or extra ring in the form of an annular wedge, and so placed within the piston and behind the three ordinary annular springs or packing, that as the said springs lose their expansive force and become weaker, and in consequence of wear the two outer rings become of less diameter, the annular wedge-formed spring is caused to exert an outward force upon them, and thereby maintain perfect contact between the cylinder and piston. The expansive force of this wedge may be increased to any required extent by steel "set screws." *Patent completed.*

310. H. C. JENNINGS. "Improvements in the manufacture of paper and artificial parchment, and of gelatine applicable to the sizing of the same, and other purposes." Dated Feb. 3, 1859.

This relates to the manufacture from the fibrous parts of fish, of a paper or parchment, and of a gelatine suitable for sizing the same. *Patent completed.*

311. J. PETRE, jun., and T. WRIGHT. "Improvements in machinery or apparatus for washing rags and other materials for the manufacture of paper." Dated Feb. 3, 1859.

This invention is not described apart from the drawings. *Patent completed.*

312. S. D. DAVISON. "Improvements in locomotive steam engines." Dated Feb. 3, 1859.

This relates to tank engines, and the main improvement consists in forming the sides of the tank by the longitudinal side-frame plates of the engine. *Patent completed.*

313. A. G. POOLEY. "Improvements in preparing fish for manure, and in apparatus for the same." Dated Feb. 3, 1859.

This consists in submitting the fish to the action of steam, and subsequently to pressure. The apparatus consists in perforated cylinders, having pistons working in them for the compression of the fish. Suitably arranged pipes convey the steam to the cylinders. *Patent abandoned.*

314. M. SMITH. "Certain improvements in looms for weaving." Dated Feb. 4, 1859.

This relates, 1, to those looms in which a jacquard or index machine is used for working the heads in combination with a box containing two or more shuttles. When a chain of lags with pegs is used to act on the hooks which work the heads, the inventor makes use of a series of pegs on the same lags, which act on a lever when a change in the shuttle-box is

required, and liberates a catch lever by which the mechanism for working the chain of tappets is brought into action. As soon as the requisite change in the position of the shuttle-box has been effected, the catch lever is again held by the lever actuated by the pegs, and the parts remain in action until another peg on the chain of lags again liberates the catch lever, and the position of the shuttle-box is then again changed according to the shape of the next link in the tappet chain. When jacquard cards are used to act on the heads the inventor produces the requisite changes in the position of the shuttle-box by a needle acted upon by the jacquard card. It relates, 2, to a patent granted to W. B. Hayes 14th September, 1854, and consists in supporting the axes of the endless chain shuttle-box by a star wheel, and in machinery for stopping the loom when the shuttle fails to enter that compartment of the shuttle-box that is in a line with the shuttle rail. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 12, 1859.

1654. T. Wright. Improvements in the permanent way of railways, and in the means of preventing accidents thereon.

Dated July 30, 1859.

1770. H. J. Newcombe. An apparatus for heating or warming buildings.

Dated Aug. 1, 1859.

1782. E. de Bassano. Improvements in the manufacture of artificial fuel, commonly called patent fuel.

Dated Aug. 5, 1859.

1802. B. Tweedy. An improved mode of and apparatus for consuming smoke in locomotive and other engine furnaces, whereby coal can be used instead of coke.

Dated Aug. 6, 1859.

1812. W. R. Drake. An apparatus for conducting electricity in the sea, and for telegraphing and sounding in deep water. (A communication.)

Dated Aug. 9, 1859.

1848. J. Waite. Improvements in making infusions for pharmaceutical purposes, which improvements are also applicable to other purposes of a similar nature.

Dated Aug. 11, 1859.

1858. W. White. A four-wheeled safety sociable carriage.

Dated Aug. 16, 1859.

1888. J. H. G. Rex. Improvements in the construction of dwelling-houses or other buildings, for the purpose of facilitating the escape of the inmates in case of fire.

Dated Aug. 17, 1859.

1892. J. Sidebottom. Certain improvements in power looms for weaving.

1896. S. Beardmore. Improvements in electric batteries.

Dated Aug. 18, 1859.

1898. W. Grimshaw and S. Mason, jun. Improvements in machinery and apparatus employed in washing, bowling, bleaching, and preparing flax, and other substances.

1900. A. J. Canu. Improvements in machines for breaking or crushing stones, minerals, or other similar materials.

Dated Aug. 19, 1859.

1904. P. Salmon. Improvements in locomotives, and in apparatus for warming trains of carriages connected thereto.

1905. W. T. Henley. Improvements in machinery for the manufacture of ropes and cables, and for paying out and picking up submarine telegraph cables.

1906. S. Boulton. Improvements in the means of, or apparatus for retarding railway carriages.

1907. J. Jackson and J. Thorley. Improvements in hoists for raising and lowering weights.

1908. J. Fowler, jun., R. Burton, D. Greig, E. E. Allen, and W. Worby. Improvements in ploughs, cultivators, or tilling implements, and in machinery for giving motion to the same by steam power.

1909. H. W. Harman. Improvements in steam boilers, and in working the same, and in safety valves, and apparatus connected therewith.

Dated Aug. 22, 1859.

1911. E. Haddon. Certain improvements in looms for weaving.

1912. W. Finegan. Improvements in apparatus for lubricating machinery.

1913. D. Grant. Improvements in wet gas meters.

1914. G. W. Petter and T. D. Galpin. Improvements in printing presses.

1915. W. A. Vérel. Improvements in the preparation of bones for manure.

1916. R. A. Brooman. Improvements in apparatus for preparing and spinning fibrous materials. (A communication.)

1917. J. J. O. Taylor. An improvement in the separation of siliceous matter from iron.

1918. H. Spratt. Improvements in revolving pistols and other fire-arms.

1919. Hon. W. Talbot. An improved cigar lighter.

1920. H. Parkes. Improvements in the manufacture of cylinders, and tubular or hollow bodies of copper, and alloys of copper or other ductile metals.

1921. E. Abbott. Improvements in ordnance and fire-arms.

1922. O. Maggs. Improvements in taps, cocks, or valves.

1923. R. S. Harvey. Improvements in apparatus for dusting vines, hops, and other plants and trees with sulphur, and other powder.

Dated Aug. 23, 1859.

1925. P. F. C. de la Salle. A new method of arranging the keys on the fingerboards of pianos, organs, and other similar instruments.

1927. T. Fry. The application of enamelled slate to the new purpose of lining, panelling, or otherwise facing the internal or external walls of houses, public buildings, and edifices generally.

1929. O. Maggs. Improvements in apparatus for weaving straw, rushes, and other materials into fabrics.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

1912. M. Billing. An improved mode of ornamenting and finishing certain articles of hardware. Dated Aug. 26, 1859.

1944. M. J. Stark. Producing a new chemical or artificial manure from bones, and all such animal and fatty matters. Dated Aug. 26, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Sept. 6, 1859.)

1019. W. Dicks and W. Hopwell. Boots and shoes.

1035. J. Holmes. Boots and shoes.

1044. W. Mackenzie. Printing impressions.

1053. G. Pearson. Trenchails.

1068. N. Libotte. Steam brake.

1069. N. J. Holmes. Electric telegraphs.

1070. E. Lardenois. Pulp. (A communication.)

1071. T. Clarke. Sheaves or pulleys.

1077. J. W. Welch. Dressing yarns.

1078. H. Bosshard. Motive power.

1081. T. Smith. Cultivating implements.

1085. E. Francis. Treatment of tea.

1092. T. H. Arrowsmith. Carding engines.

1100. D. Moore. Dressing types.

1106. T. W. Miller. Generating steam.

1115. R. Mushet. Cast steel.

1122. H. Turner. Steam-engines.

1123. J. F. Allender and D. Bowley. Shears.

1150. R. Mushet. Puddling iron and steel.

1151. R. Mushet. Iron.

1154. W. E. Gedge. Steel. (A communication.)

1161. G. G. Bussey. Carrying cartridges.

1182. H. Clarke. Mill stones. (A communication.)

1183. M. Henry. Mariner's compass. (A communication.)

1197. W. Clark. Knitting machines. (A communication.)

1251. W. C. Cambridge. Thrashing and winnowing.

1560. N. Ardaseer. Steam boilers.

1617. W. Robinson. Cask-washing machines.

1645. H. Davies. Soap.

1654. T. Wright. Permanent way.

1661. J. Combe. Hackling fibres.

1718. J. Hartley. Steam-engines.

1778. E. Merrell. Washing and cleansing.

1808. R. T. Pattison. Dyeing fabrics.

1822. J. Cunningham. Jacquard apparatus.

1836. J. Cannon. Washing machines. (A communication.)

1856. W. White. Sociable carriage.

1860. W. De la Rue and H. Müller. Treating wax.

1900. H. W. Harman. Steam-boilers.

1944. M. J. Stark. Manure.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed August 31, 1859.

441. S. T. Cooper.	645. C. H. Hurst.
546. J. T. Carter.	653. W. Clark.
553. J. W. Harker and J. K. Field.	657. W. Robertson and J. G. Orchar.
554. E. Roche.	708. W. C. Cambridge.
560. H. Brown.	709. W. Hudson and C. Catlow.
566. J. D. Dougall.	721. W. A. Gilbee.
573. C. E. Dennet.	754. H. Rigby.
578. R. A. Brooman.	780. W. Mossman.
579. J. M. Dunlop.	800. A. V. Newton.
582. F. W. Parker.	818. W. E. Newton.
588. R. Leake and M. Sykes.	830. A. Pagot.
592. W. Palmer.	935. J. Luis.
594. W. Gossage.	993. J. Wotton.
595. J. Aspinall.	1000. J. Holroyd.
599. J. L. Jullion and G. Pirie.	1410. F. Puls.
601. A. Booth and A. Booth, jun.	1420. F. A. T. de Beauregard.
603. G. Twigg.	1497. R. Smith.
610. J. A. Williams.	1521. R. Hornsby, jun.
612. J. R. Nicholson.	1561. L. L. Tower.
626. R. Hecclard.	1598. J. H. and T. Nalder.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

2016. J. Blake and F. Maxwell.	2062. Earl of Aldborough.
2037. J. Apperly.	2064. J. B. Dancer.
2039. P. J. Guyet.	2068. W. S. Mitchell and C. M. E. Gärtner.
2046. E. P. Spiller.	2070. R. Wilson.
2054. E. and G. P. Leigh.	2076. S. W. Park and E. S. Ellis.

LIST OF SPECIFICATIONS, &c.,

Published during the week ending Sept. 2, 1859.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS IN VITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

GAS-WORKS, Blackburn.—For the erection at No. 2 station, Addison-street, of a circular Ashlar stone tank, the diameter of which to be 112 feet, and 30 feet 6 inches in depth, including also dry well, river and retaining walling in connection with same. Plans, specifications, and conditions at the Company's office, Jubilee-street. Tenders, 26th September, to C. Parkinson, Esq., Chairman to the Blackburn Gas Light Company.

Dikes, Scotland.—For building about 200 rods of dikes, on the lands of Holeshiel, in the parish of Humble, East Lothian, according to specifications with Mr. Hyslop, tenant at Holeshiel. Estimates to Messrs. Lawse and Bonnar, W. S., 15 York Place, Edinburgh (who will also show the specification) September 20.

TILES, Scotland.—The magistrates and town-council of Forfar require the following tiles,—70,000 pipes and collars of 14-in., 600 yards of 3-in. tile, 800 yards of 4-in., 1,400 yards of 6-in., 200 yards of 8-in., and 300 yards of 10-in. Tenders to Mr. George Patterson, Superintendent, Forfar, September 14, with specimens. The whole to be delivered by the 1st of January next, and delivered at Forfar, or the Southmuir of Forfar.

CAST-IRON WATER-PIPES, Ifracombe.—Contract No. 1 for 200 tons of cast-iron water-pipes. Contract 2, for the supply of sluices, hydrants, &c. Contract No. 3, for excavating the ground, and laying 5,300 yards of water mains. Contract No. 4, for construction of a covered reservoir, &c. Drawings and information at offices of Mr. Langdon, Solicitor, Ifracombe, or at the office of Mr. Whitehead, County Surveyor of Somerset, Weston-Super-Mare. Duplicate copies and forms of tender at either of the above offices on payment of 10s. 6d. for contracts No. 1 and 2, and £1 1s. for Nos. 3 and 4. Tenders to September 19th.

COPPER SLIPS, India Board.—Conditions on application at the Secretariat office up to the 13th inst., where proposals before 11 a.m.

DRAINAGE AND WATER WORKS, Hants.—For carrying on Drainage and Water Works at Fareham, Hants. The works will consist of about 4½ miles of Stone Pipe Sewers, Deodorizing Tanks, &c., and about ½ mile of Iron Water Mains, Water Reservoir, Pumping Engines, &c. The contract for the pumping engines will be let separately. Plans, &c., Mr. E. Rutledge, Engineer to the Fareham Local Board of Health, Quay-street, Fareham. Tenders, R. Porter, Esq., Chairman of the Board, September 14.

CHURCH, Horncastle, Lincolnshire.—For the restoration and reseating. Drawings, Mr. Nicholson, Churchwarden, and at office of Mr. Christian, architect, 10 Whitehall-place, London, S.W. Tenders to September 30.

SEWERS, Greenwich.—Also a reservoir and pumping station, engines, machinery, &c. Plans at office of the Metropolitan Board of Works, No. 1 Greek-street, Soho Square. No date given.

RESTORING CHURCH, Lincolnshire.—For restoring and reseating the old parish church of Horncastle, Lincolnshire. Plans, &c., until September 20, Mr. H. Nicholson, Churchwarden, and at the office of the architect, Mr. Christian, 10 Whitehall-place, London, S.W. Tenders, September 30, Chairman of the Church Committee, Vicarage, Horncastle.

CHAPEL, Southampton.—Drawings, office of Messrs. Hayley and Sons, architects, Cross-street, Manchester. Tenders to September 20th.

PARSONAGE HOUSE, Ambleside, near Stourbridge.—Plans, office of Mr. J. M. Gething, Dennis Park, Eriehley-hill. Tenders to Rev. J. M. Grier, Stourbridge, to September 19th.

WORKHOUSE, Swansea.—The time has been extended to the 14th inst. Whole or any part of works. Lithographed bills of quantities prepared by Messrs. Pearson and Doughney, surveyors, 9 John-street, Adelphi, London, may be obtained either at their offices or at the workhouse, Swansea. Tenders to clerk to guardians, to 5 Fisher-street, Swansea.

HOTEL AND TAVERN, London.—On the Vauxhall gardens estate. Plans and particulars at the office of Mr. W. W. Munford, architect, 21 Lincoln's-inn-fields. No date given.

WORKSHOPS, Dublin.—For the erection of workshops and other buildings on the premises of the North Wall Graving Dock, conformably to the specifications, &c., to be seen at the Ballast Office, of the Corporation for Preserving and Improving the Port of Dublin, where also printed forms of tender. Proposals to Mr. Wm. Lee, secretary, September 20.

SCHOOL-ROOM, &c., Hants.—For the erection of a school-room, with quarters for schoolmaster and schoolmistress, Christchurch Barracks, in the county of Hants. Plans, &c., Royal Engineer Office, Gosport, to September 17. Tenders, War Office, Pall Mall, September 19.

DESIGN FOR GUILDHALL, Cambridge.—A premium of £200 will be given for the best, and £100 for the second best. Printed particulars at office of the town clerk, Cambridge. Designs to October 31st.

PLANS, &c., FOR CEMETERY.—Including roads and approaches, two chapels, gates, lodge walls, &c., premium, £15 for the best plan, and £10 for the next, to be left at office of Mr. A. D. Bartlett, clerk to the burial board, Abingdon, to September 21st.

SURVEYING, Brecon.—For making a survey and plan of the town of Brecon, on a scale of five feet to a mile, for the purposes of the Public Health Act, 1848, and of the Local Government Act, 1858. Printed terms, &c., Mr. Kirk, surveyor to the board. Tenders, S. B. Evans, clerk to the board, September 14.

IRONWORKS MANAGER.—Small ironworks. Apply by letter to Mr. R. Bewley, Stoke-on-Trent, stating salary and reference to last place.

WIRE DRAWING MANAGER.—A thoroughly practical man, well qualified to manage a wire drawing establishment. Address, T. 41, Journal office, Birmingham.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 16, 1859.

THE GREAT EASTERN.

MONDAY, Sept. 12, 1859.

IN the late passage of the Great Eastern from the Thames to Portland, with the terrible episode of a deadly explosion, there is much that seems to require our attention. The remarks which we transmitted from the ship for publication in our last number will have acquainted our readers with the prosperity and promise of the journey from Deptford to the Nore. Our present observations will therefore be directed to what happened during the completion of the passage from that point. And in carrying out our design we shall not enter upon any detailed narrative of that eventful trip. The rapid run to the Downs against a driving wind—the steady progress down the Channel through a gale which no other vessel faced—the joy and confidence with which all on board beheld the mastery man's genius had at last gained over wave and storm—then, the sudden explosion, the crashing down of the funnel, the rushing of the steam, the bursting up of the saloon, the alarm of fire, the activity of the officers, the steadiness of the passengers, the rescue of the scalded firemen, the devotion of the surgeons, the gradual return of confidence, the continuance of the voyage, the deaths of the sufferers, the arrival at Portland, the greetings from all around the ship, the silence of all within her—all these things have been faithfully and ably told by the special correspondents of the daily press, and need no repetition here. But connected with these occurrences there were others which fall within our professional sphere, and which, if they are not dealt with efficiently here, will probably not be dealt with efficiently at all. To these, then, let us turn.

And first, let us state that the cause of the explosion which occurred has not been correctly described, we believe, by the correspondents of the daily press. It is quite true, as has been said, that the vessel which burst was formed by the uptake or funnel on the inside and by a casing on the outside; and also that while the primary object in forming this chamber was to prevent the heating of the saloons, a further advantage was gained by feeding the boiler from the water which the chamber contained. This water, being supplied to the chamber cold, and drawn off when heated by the waste gases passing up the uptake, first had the effect of keeping the water-casing cool, and afterwards (when heated) was readily converted into steam in the boiler. So far the newspaper accounts are correct. But when they proceed to tell us that "the safety of the whole affair depends upon the stop-cock which lets off the water into the boilers being watched with unremitting vigilance," and that "the neglect of this for half-an-hour would allow steam to generate in the casing, which would then, in plain terms, become a gigantic boiler, without a valve or any means of letting off its steam save by blowing up"—when, we say, they tell us this, and add that it was the neglect of turning the aforesaid stop-cock that occasioned the accident, they fall into error. The fact is, the "gigantic boiler" was not without a valve

for letting off any steam that might be generated in it; on the contrary, it was furnished with such a valve, or rather with a tap, and this valve or tap opened into a small stand-pipe which was led up by the side of the main blow-off steam pipe of the boiler. Why the pipe alone was not sufficient, and why it had a tap fitted to it we cannot divine. But such a tap was fitted, and unhappily, on the occasion in question, it was either closed or left closed—by whom, or by whose dire neglect, the inquest upon the dead alone can be expected to reveal—and, consequently, when the engineer ceased to feed from the chamber, steam was generated and found no escape. Hence the accident which all men must deplore!

And before proceeding further, let us do an act of simple justice to Mr. Scott Russell, by preventing a misapprehension which may easily arise. It is thought by some that the responsibility of the arrangement above described rests with that gentleman, as the builder of the paddle-wheel engines; the more so because a similar arrangement was excluded from the boilers used for the screw-engines of Messrs. Boulton and Watt. But this opinion is utterly false. We have proof as positive as can be desired to the effect that for the arrangement in question Mr. Russell is not in the remotest degree responsible. It was adopted by the Company on the recommendation of their own engineer, and was carried out by the Company in entire independence of Mr. Russell as the builder of the paddle-engines. We are the more anxious to enforce these facts, because those engines themselves—by far the largest in existence, and for which Mr. Russell is solely responsible—are unquestionably one of the most magnificent and successful features of this magnificent and successful ship. On the whole journey from Deptford to Portland, the astonishing ease, the constant uniformity, in a word, the absolute perfection with which those huge machines worked, excited the unceasing admiration of some of the foremost engineers in the whole world, several of whom were on board. When this is understood, and when it is further remembered that the noble hull, which withstood the tremendous shock of that great explosion absolutely unharmed, was also the work of the same man, all will feel how unfair it would be to detract from the credit of such successes by any error on the point in question.

Nor let us be content with doing justice to one individual. Let us do it also to the Company's engineer, by saying that nothing within our present knowledge places the responsibility of the late accident upon him. The arrangement of water-casing described may be, and we believe is, a bad and dangerous one; but, let it be observed, the thing itself was not in this instance the cause of the disaster. It was either the unwise adoption or the bad management of a mere detail—the valve or tap—that caused the explosion, and no evidence has yet been produced to show who was guilty of that unwise adoption or that bad management. This we laboriously endeavoured to ascertain on board the ship after the accident, but without avail. Clearly, however, the Company's engineer may be entirely free from blame in the matter. At the same time, as other dangers attend the use of the feed-water casing, we hope it will be altogether done away with in the Great Eastern for the future.

And now, before we turn from this subject of the explosion, let us advert to certain circumstances which followed that event, and which reflect great discredit upon some few of the passengers who are pleased to call themselves engineers. Some of the morning papers have printed the following document, which was

issued before the company left the ship in Portland harbour on Saturday last. It runs:—

"Great Eastern Steamship,
Portland Harbour, 10th Sep., 1859.

"Yesterday, at six p.m., an accident occurred on board the Great Eastern. The feed-water casing of the foremost chimney collapsed, owing to some neglect. Several stokers were seriously scalded; three since dead. No passengers injured. The ship and machinery are uninjured except main cabin fittings which are damaged. The working of the engines continued, and the ship proceeded uninterruptedly on her voyage to Portland.

"J. SCOTT RUSSELL, "J. E. McCONNELL,
"R. P. BRETON,
"—BRETON,
"F. P. SMITH,
"W. SMITH,
"W. WOLLASTON BLAKE."

It is incumbent upon us to record the history of this very ridiculous production—ridiculous because while it pretends to be a professional document, and bears the names of men all of whom are either real or pretended engineers, it does not state a single fact that was not known to every soul on board the ship long before it appeared. The manner of its concoction will be gathered from the following statement:—Up to the time of the explosion, the success of the Great Eastern was felt by all on board to be fully assured. The rate at which she travelled, with engines at half-speed only—her perfect steadiness in heavily-rolling seas—the ease and readiness with which she answered her helm—the absence of all vibration in her splendid saloons—all these things, and some others, had made it plain that in all her mechanical features the vessel was a complete triumph. When the explosion came, a brief, but strong revulsion of feeling ensued. In accounting for this let us state our own personal experiences in the matter. About a dozen passengers, including Mr. James Nasmyth, the celebrated engineer, Mr. McConnell, the locomotive engineer, Lord Alfred Paget, three or four literary gentlemen, and ourselves were right forward in the bow, sitting in the shelter of the topside; and having decided that the ship was mechanically a success, were about to discuss her commercial prospects. Lord Paget was uttering the last word of a sentence when a loud report, and a fearful throb through the ship beneath us, in an instant turned all our eyes aft. They were so turned only to behold the foremost funnel fly upward, followed by a cloud of steam driving the wreck of the grand saloon before it. Our first impression was that the boiler itself had burst, but something in the sound of the report made us think that the bottom of the ship had successfully resisted the shock. Of this we could not, of course, assure ourselves until considerable time had elapsed. Being situated before the scene of the explosion, with a high wind driving aft, there was nothing to prevent our rushing at once to the spot. This we accordingly did, in sufficient time to hear the first cries of agony, and of fire also, from below. Steps were at once taken to rescue the firemen from the stokehole; but ere more than two or three of the unfortunate men were brought up (in a condition which we need not describe here) our attention was called off by an excessive activity at the ship's side. This arose from an attempt which some of the riggers were making to lower a boat—whether to save a frightened nobleman, as some say, or to rescue a man who had leaped overboard, as others say, we cannot positively state. But we at once saw that the paddle-wheels were still going, and that the boat was being lowered immediately in front of them. One word whispered in the ear of Captain Harrison sufficed to have this monstrous folly checked, and the boat restored

to its place. The removal of the hysterical wife of a director, who was rushing wildly in the thick of the turmoil screaming for her son, with the restoration of both son and husband to her, and other circumstances of the kind, varied the business of the moment, but need no record here. A considerable time—nearly a quarter of an hour—elapsed before either the Captain, Mr. Russell, the Chairman of the Company, or any other official person of note on board, became positively assured that there was nothing to apprehend from fire. There was no panic, or anything of the kind, so far as we observed—no considerable fear, even; but that further danger was supposed to exist for the time we have named is, we believe, quite true. Moreover, until it became known that there were no less than three medical men on board many thought it the duty of those in charge to take the ship into the nearest port; but after this was known, we heard nothing more upon the subject—except from the gentlemen of the press, who naturally enough would have been glad of an early opportunity of making the occurrence known to their respective journals.

Now, from what we have said, as well as from what the newspaper correspondents have said before us, it will be seen that a disastrous "blow-up" occurred. Evidences of the force by which that blow-up was effected were to be seen as soon as the excitement had subsided; first, in the utterly crushed-up condition of the up-take or lower piece of funnel within the casing, and, secondly, in the fact that this mass of metal, weighing a ton or two, had been blown bodily up from below. Equally strong evidences were to be seen in the lower parts of the ship. That the delight which pervaded the minds of all on board up to the moment of the explosion was now succeeded by a general gloom will be readily believed; and it will also be readily understood that none felt really more depressed than the Directors of the Company, to whom the commercial success of the vessel was of the greatest moment; but, like men of business, they—and especially Mr. Campbell, the Chairman—at once set about considering how the best of a bad thing was to be made. The persons with respect to whom they of course became deeply solicitous were the "gentlemen of the press"—chiefly those of the daily press. We had representatives of the *Times* and half-a-dozen other daily papers on board, and as the despatch of telegrams announcing the accident to the world, and also of papers describing it to the world, rested with these gentlemen, very much depended upon the impressions produced upon their minds. In order to modify those impressions—in so far, at least, as an accurate statement of the facts of the case in a scientific manner could modify them—the Chairman and his colleagues determined upon appealing to a scientific man to make such a statement. Accordingly Mr. McConnell, the locomotive engineer, was requested to prepare himself for the purpose. This he did, and at 11 o'clock on Friday night—five hours after the accident—the representatives of the press were assembled in the Chairman's cabin to receive his statement.

Now, Mr. McConnell's duty in the matter should have been plain enough to him. It was, undoubtedly, to have stated as accurately as he could the nature of the apparatus which had produced the mischief, and to have shown, as nearly as he was able, the cause of its failure. He might then with truth have said that the apparatus which had burst formed no integral or necessary part of the ship—that there was but one other of a like nature on board, and

this could readily be removed—that the bottom of the ship had sustained the shock without the least injury, thereby showing wonderful strength—that notwithstanding the alarm of the evening, the ship had been in no sort of danger from fire—that the mischief was really circumscribed within very narrow limits—and that altogether, although the disaster was to be deeply regretted on account of the sufferings and deaths occasioned by it, the inference to be drawn from a survey of the vessel was, that the hull of the Great Eastern had borne unharmed an explosion which would in all probability have sent any other ship to the bottom. All this might have been said, and the only effect produced would have been that of helping the gentlemen present to publish a dispassionate account of what had transpired. There would have been nothing in it to offend either their pride or their good sense.

But Mr. McConnell—with whom, for some mysterious reason, Mr. F. P. Smith got associated in the business—acted quite otherwise. It will scarcely be believed, but it is nevertheless true, that, in his first words, he said he "desired to disabuse the minds of the gentlemen present of the belief that an explosion 'had taken place.'" "There has been," said he, "no explosion, but only a collapse of a water vessel." When it is remembered that correspondents of the press almost invariably consider themselves thoroughly independent, honourable, and excessively clever fellows, the effect of Mr. McConnell's announcement may be imagined. It was, of course, met not only with stout resistance, but with derision; and was followed by an hour of most unprofitable talk, ending with the promise of a report signed by Mr. McConnell and Mr. F. P. Smith in the morning. On our part we opposed this proceeding, urging the production of a report for which Mr. McConnell, or some other engineer alone, should be responsible, or else of a report from a committee formed of several of the scientific men on board. It should be remembered that we had Mr. Nasmyth, Mr. Appold, and other eminent men on board the ship; and there can be no doubt that had the object of the proceeding been fairly and justly carried out, we should have had a truly scientific report framed before we left the ship. As it was, a draft of a statement even more absurd than that afterwards produced was brought forward, but was withdrawn on the opposition of a literary gentleman, who pronounced one of its clauses "a lie," and most of the others unfair. Finally, the precious document printed above was produced, and signed by some who would sign anything to get their names in print—men who will have a finger even in a dirt pie—and also by Mr. Blake and Mr. Russell, whose names were afterwards put to it, probably to save trouble, and because the paper meant nothing. We state all these facts only for the sake of denouncing them; we state them only that we may follow them by saying that, from first to last, Mr. McConnell and his officious colleagues on this occasion, did nothing but degrade science and put really scientific men to the blush. The whole of their proceedings, from the moment when reference was first made to them until we left the ship, were in the highest degree discreditable to them as professional or scientific men. We should say this had we been entirely unsupported in our opinions; but we say it all the more readily because the really scientific men who were on board are looking to us for a firm protest on the subject.

Having disposed of these scientific (!) proceedings, let us now remind our readers that the disaster of Friday evening last in no way detracts from the intrinsic merits of the Great

Eastern, or lessens the success which her builder has achieved. What her full speed will prove to be cannot be foretold; her trial trip to Cherbourg will have that to decide. That trip will also have to determine by what expenditure of fuel—and generally with what degree of economy—her full speed is to be attained. But when it is remembered that on her way round to Portland the paddles where at no time permitted to make more than $8\frac{1}{2}$ revolutions per minute or her screw more than 30, and that she nevertheless attained a speed of more than 12 knots against a strong head wind, we have good grounds for expecting great things of her when she shall be allowed to do her best. It should be remembered that those extravagant expectations—of 22 and even 24 knots per hour—which we so often hear of on all sides in connection with this subject, have never proceeded from persons authorised to speak upon the subject. Mr. Scott Russell modestly names 15 knots as a fair speed for her; and when her power is compared with that of other vessels there is really no reason for calling this too low an estimate. But it is already pretty certain that she will considerably exceed it; let us hope she may. But what she is able to do in respect of speed must of course depend, to a great extent, upon the capabilities of her screw engines, and we are sorry to say we feel rather doubtful as to them. They are unfortunately horizontal engines, and very similar to those fitted by Boulton and Watt in screw ships of war. For such ships it is, of course, absolutely necessary to keep the engines low, and there is good reason therefore for adapting horizontal engines to them. But there was no kind of necessity for fitting such engines in the Great Eastern. We should have very much preferred to see her furnished with engines of the form now largely in use on the Clyde, the plan of which may be said to be a modification of Mr. Nasmyth's hammer engine. In the arrangement to which we refer the cylinder is placed above the screw shaft, and from the piston rod a long connecting rod extends down to the shaft. A light hollow frame carries the cylinder, and a cross-head on the piston forms a guide, sliding up and down between the opposite sides of the frame. The hollow frame itself forms the condenser. Engines of this construction work with great smoothness and sweetness—more than can ever be hoped for from the screw engines of the Great Eastern—and such engines might have been adapted to her with the utmost convenience. It must also be admitted that the present engines manifested much uneasiness on the trip to Portland—an uneasiness which we sincerely hope may not reappear on the next trial.

Several of those writers for the daily press who have most admired the steadiness of the ship on her last week's voyage, seem to imagine that when, by the breaking of the steering lines, command of her was temporarily lost off Beachy Head, she rolled and pitched very heavily. This was not so. A real and manifest motion was undoubtedly imparted to her when she fell off from the wind, but it was so slight that it would scarcely have been noticed at all in any other vessel. For our part we are quite convinced, from the experience of last week, that the Great Eastern, if properly handled, will disappoint no one in the matter of steadiness in a seaway. Our meals were taken throughout the journey down Channel without our being once reminded, by any movement of the service, that we were on board a ship at all,—and yet we were really in the midst of high winds and turbulent seas. We must add to all this the perfect ease and readiness with which this huge monster steers, in

order to fully appreciate her qualities as a sea-going vessel.

WEDNESDAY, Sept. 14.

In the evidence given at the inquest on Monday last, as reported in the morning papers, the accuracy of our former remarks (written on Monday) is fully established. It appears that the tap and stand-pipe were really fitted as we said, and the difficulty we had in accounting for the existence of a tap in such a pipe is removed by the statement that it was put there to enable the engineers to test the funnel-casing by hydraulic pressure. It is therefore pretty evident that the cause of the accident will ultimately be traced to some individual or individuals. We account for the mistake made by the newspaper writers in their accounts of the accident by assuming that they mistook the top of the length of casing which was blown upon the deck for the top. This is certainly what some persons did—a Metropolitan Member of Parliament, for instance, who was on board, and who displayed great skill and ingenuity in discussing with us the cause of the accident; and this, probably, is what the gentlemen in question did also.

It would also appear from the evidence given by one of the witnesses on Monday last that Mr. Scott Russell had charge of the boilers at the time of the accident. If he had, it cannot be supposed that an engineer taking temporarily the general control of a ship's boilers is to be held responsible for the condition of a tap which was "boxed up" or cased in many days before, and which, as a matter of course, should have been open, and afforded no sort of indication that it was not so. But we believe it to be altogether a mistake to suppose that Mr. Russell had anything whatever to do with the charge of the boilers on the trip. What he took upon himself—in our own hearing, in the first instance, as it happens—was the duty of communicating between the pilot or captain and the engine-rooms, in order that no bungling or risk might happen in consequence of imperfect or contradictory instructions reaching the engineers in charge of the paddle-wheel engine and the screw engine respectively. For this purpose he took his station upon the paddle-bridge, and stuck to it—incessantly from London to the Nore, and all but as incessantly from the Nore to the Downs, all the while the ship was under weigh. How it is possible for any one to suppose that a gentleman stationed there, and having charge of the telegraphs to both engine-rooms, can have been at the same time responsible for the details of the various boilers also, passes our understanding. We believe the witnesses must have been altogether mistaken on this head, and look anxiously for further intelligence on the subject.

THURSDAY, Sept. 15.

We have already guarded our readers against accepting the statements made by the witnesses at the inquest on Monday (supposing them to be correctly reported in the *Times*) as altogether fair and true. As matters advance, the necessity for caution in this respect appears to increase; and we begin further to fear that we must look to other newspapers rather than to the *Times* for full, and even for fair, reports of what transpires at Weymouth. In confirmation of this we would remind our readers that, in the absence of Mr. Scott Russell on Monday, the witnesses spoke and the *Times* reporter reported in such a manner as to indirectly but seriously implicate that gentleman. In the *Times* report of to-day not a word appears to counteract the impression thus produced; nor is Mr. Russell, although present yesterday, represented as expressing any dissatisfaction with Monday's proceedings. But when we turn to a "penny

paper"—the *Morning Star*, which has reported upon the various features of this case with singular moderation and fairness—we find that (although the fact is suppressed in the *Times*) Mr. Russell did object to the evidence given on Monday, or rather to the endeavours which the Company appear to be making to colour the facts of the case, and said "he was decidedly at issue with the Company upon some points relative to the inquiry."

If we may be allowed to offer a suggestion to the Company we would advise them—and especially their young and inexperienced solicitor, Mr. Leverson (or Levy-son, as we think the correct name is)—not to run to excesses through an undue anxiety to protect the Company at the expense of the illustrious builder of the ship, or of any one else. It is perfectly evident from the *Morning Star's* report of this day that the coroner is already alive to their danger in this respect, and has offered a gentle warning, which we hope the solicitor will avail himself of—witness the following conversation:—

A Jurymen: Mr. Scott Russell I suppose is aware that the imputation is that the man who lengthened the stand-pipe screwed in the tap of the water-casing, and so left it.

Mr. S. Russell: Yes; but I think it will be shown in evidence that previous to the sailing of the vessel, that cock was found open. I shall be happy to attend to any intimation from the jury as to the production of any other witnesses.

In reply to another question from a jurymen, Mr. Russell said that Mr. Dixon, the superintending engineer, would be in readiness to give evidence on Saturday.

The Coroner: Have you many witnesses to call, Mr. Leverson?

Mr. Leverson: As the case at present stands, it appears clear that, unless Mr. Scott Russell puts a different construction upon the facts to that which we have put upon them, none of the company's servants are at all to blame for this unfortunate catastrophe. At present I shall not feel it necessary upon the part of the company to call any witnesses whatever.

The Coroner: On the part of the court I can inform you that the first witness I shall think it necessary to call is Mr. M'Lennan.

Mr. Leverson explained that he was quite ready to produce any witnesses whom the coroner and jury thought ought to be examined. All that he meant to say was, that he did not intend to volunteer any evidence. He had endeavoured, and should endeavour, to show that the company were in no way responsible for this deplorable accident.

The Coroner: And I presume that Mr. Scott Russell will endeavour to show that the responsibility does not rest upon him.

Mr. Newman: Mr. Scott Russell will endeavour to elicit the whole facts of the case.

Mr. Russell: All that we wish to know is, who was the man who shut the cock which caused the explosion?

In point of fact we think it time the "Company" had given up their personal interference in the ship—time that the captain took charge of her, and held himself and his officers responsible for all that transpires in her. No confidence will be felt by the public at large until this is done. Meanwhile we may look to the resumption of the inquest for interesting information. What we suspect will be found out is, that Mr. Russell, as we before said, took charge of the engines, and of them alone; but now that life has been lost and expense incurred by an explosion in the boiler department, an attempt is being made to show that he took charge of that department also. But we have already stated why we believe this was not the case, and we have no doubt that the attempt is based upon either a sad mistake or a gross subterfuge: time will show which.

But whoever had general charge of the boilers, it is pretty evident that not he, but "the man who shut the cock which caused the

* The same report appears, we find, in the *Morning Chronicle* and other papers.

"explosion," is the blameable person; there is little need, therefore, for wrangling on the general question. As long as steam boilers are used we shall be at the mercy of mechanical workmen, and even of labourers; and this accident appears at present to be an instance of the terrible neglect of which such men, as well as others, are at times guilty.

THE ACCIDENT ON BOARD THE GREAT EASTERN.

THE following account of the inquest held at Weymouth on the bodies of the men who were killed on board the Great Eastern is condensed from the reports published in the *Times*. Those parts only which have little or no professional bearing are omitted. There is a great deal of obscurity in some of the statements of the witnesses, but as we were not in attendance at the examination we cannot say whether that obscurity arises from the imperfection of the report or not.

TUESDAY, Sept. 13.

The inquest was commenced on Monday morning on the bodies of five men, all of whom lost their lives by the late explosion. It was held at the Town-hall, at Weymouth, before Mr. Henry Lock, the Coroner for Dorset.

The jury having been sworn, and having viewed the bodies,

The first witness examined was James Briscoe, the junior engineer of the paddle-engine department, who said that it was his duty to attend to the direction of the engineer in charge of the paddle-engines on duty, and to render assistance under their direction. He was told not to meddle with or make himself responsible for any of the cocks or valves. The duty assigned to him on the morning of the explosion was to attend the boilers and keep a proper supply of water in them. He had charge of the donkey-engine which pumped into the boiler; it was out of order, and did not perform its duty satisfactorily. He stood by one of the donkey-engines in No. 1 stokehole all day to keep it doing its work. That was on the star-board side of the ship. The donkey-engine on the port side of the ship in the forward stokehole had broken down. One minute before the explosion Mr. M'Lennan, the chief engineer of the ship, came down to witness, and looked to the saturation of the water in the boilers, and said, on leaving, that everything seemed right, and again cautioned witness not to meddle with any of the cocks or valves unless told by the engineer in charge of the paddle-engine department. Mr. M'Lennan left the place, and witness resumed his place by the donkey-engine. Shortly after the explosion took place, filling the stokehole with hot air and steam, witness came up the fore stokehole ladder. Noticed, while on the lower deck, that the inner and outer casings of the funnels were burst asunder, and that the whole of the cabins were destroyed on the lower saloon. Knew that the bursting of the water-heater round the forward funnel caused the explosion.

Examined by Mr. Leverson.—He remembered Mr. M'Lennan calling the engineers and stokers together on Tuesday last. Mr. M'Lennan told witness not to meddle with the engines or boiler, but to obey the orders of the engineer in charge of the paddle-department; that the engines were in Mr. Scott Russell's hands, and that he had supplied the engineers to attend them himself. Mr. Dickson, Mr. Russell's foreman, assumed control in the paddle-department; the explosion was confined to the funnel casing, which was for heating the water before going into the boilers, and also for keeping the saloon cool. The boiler would under ordinary circumstances be fed with water from the water-casing. At the time of the explosion, the boilers were not being fed from the casing, which was evident from the low temperature of the water going into the boiler. They had ceased to feed the boilers from the water-casing, he believed, to get a greater amount of water into the boiler. If the water-casing had been regularly kept supplied with water, and a continual

flow in and out, the accident would not have happened. There were two stand-pipes to the water-casing, which, if open, would have prevented it. When the accident took place he had saved himself from being scalded to death by throwing himself down in the stokehole and covering his face with his hands. Witness knew that the engines were under the charge of Mr. Russell. Mr. Russell was on the bridge giving orders to his men below.

The Coroner asked the solicitor to the company whether any one was in attendance on the part of Mr. Scott Russell?

Mr. Leverson stated that there was no one.

Mr. Brereton, one of Mr. Brunel's principal engineers, was called to give evidence as to the probable cause of the accident. He stated that Mr. Brunel intended to accompany the ship on the trial trip, but in consequence of his illness witness accompanied the ship on his behalf. The accident occurred at six p.m. on Friday afternoon, when the ship was off Dungeness. When the explosion took place witness was near the paddle-boxes. The foremost funnel was blown up above the deck, immediately followed by a shower of splinters and pieces of glass. Went forward and found the funnel lying on deck in two parts, and on looking down the gratings leading to the boiler-rooms heard men crying for help and water. A good many of the passengers were there at the time, the fire hoses were laid on, a supply of water obtained to extinguish any fire that might have occurred; men then went below and brought up the wounded. As soon as the confusion was over examined the broken funnel on deck. On the following morning, according to the direction of the chairman, witness, with other engineers on board, examined the place where the explosion took place, to make a report as to the cause of the accident. Witness was accompanied in his examination by Mr. McConnell (the engineer of the North-Western Railway), Mr. Scott Russell, Mr. Smith (the inventor of the screw propeller), Mr. W. Smith (a civil engineer), and Mr. Bates, who represented the firm of Boulton and Watt. Witness and those with him came to a conclusion as to the cause of the accident. The double-funnel casing was not always applied to other steam-boilers. The fact of the woodwork around the funnel being blown away led witness to see the cause of the accident without the drawings or explanations. They ascertained that the funnel was double for 40 feet of its length, the inside being 6 feet diameter, and the outside one 7 feet, leaving a space of 6 inches between the two all round. The water was contained between the two; the explosion took place about half-way down, near the lower deck. The inner casing was collapsed, and the outer one burst out. The object of the casing was to prevent the water being led direct to the boilers. There was an apparatus provided to prevent any excessive pressure accumulating in the water-jacket. This apparatus consisted of a "stand-pipe," which was carried to near the level of the top of the funnel, and communicated with the water-jacket, constituting a safety-valve. Being open at the top, as soon as the pressure increases it runs out of the "stand-pipe." The height of the column of water regulated the pressure in the jackets. From inquiry they learned that the feed water for the boiler was sent direct to the boiler without passing through the funnel, as the donkey engines did not work satisfactorily; one of them being disabled, the other had to do the work of two. That accounted for the fact of the communication between the boilers and the casing being shut off. An explosion ought not to have occurred if the "stand-pipe" was in operation. Their attention was called to the state of the stand-pipe, and they found at the bottom of it a plug capable of being turned. It was shut off, leaving no vent for the steam generated in the case. If the "stand-pipe" had been in operation, or if the feed was continued through the jacket, the explosion would not have occurred. The steam must have gone on generating till the cylinder burst. No

one seemed to know how, when, or by whom the cock was shut. Two or three days before the ship sailed, the "stand-pipe" not being high enough, a piece was added to it, so that up to that time the cock must have been open. It was supposed to have been closed by some workman for some purpose, and not to have been again opened.

By a Juror.—There was no safety or other valve to show there was pressure in the case, as the pipe should always be open. Mr. Dickson was the engineer under Mr. Scott Russell directly responsible for the making and working of the engines. The engineer believes the cock never was opened from the time of leaving the river. If the cock had been taken off the accident could never have happened. The cock was put on to test the cases by hydraulic pressure, and had not been removed. The cock could not have been closed by the force of the explosion, or, indeed, witness could not conceive the accident occurring.

The court then adjourned to 9 o'clock on Saturday morning. The jury and the Coroner proceeded to examine the part of the ship where the accident occurred.

WEYMOUTH, WEDNESDAY, Sept. 14.

To-day, at 2 o'clock, the adjourned inquiry was resumed. The investigation appeared to excite no great amount of interest, and the court was almost empty throughout the entire proceedings.

Mr. J. Scott Russell, in compliance with a wish expressed by the Coroner, came down from town to attend the inquest.

Mr. John Dickson, foreman to Mr. Russell, and under whose superintendence the machinery of the paddle engines was fitted, was also present, and Mr. McLennan, the chief engineer of the Great Eastern.

Mr. Newman (of Freshfields and Newman) attended to watch the case with Mr. Scott Russell. At the commencement of the proceedings Mr. Leverson, the solicitor to the company, said he wished to correct an error which had appeared in some of the papers to the effect that he (Mr. Leverson) had stated at the previous inquiry that Mr. Scott Russell had had ample notice to attend the opening of the inquest, but had not done so. In fact, what he had stated was exactly the reverse, namely, that Mr. Scott Russell had had no notice of the inquiry; that he was at the time in London, on the company's business, and could not possibly have been in attendance.

After a few words from Mr. Scott Russell, who explained the cause of his unavoidable absence [and, as reported in the *Morning Star*, added that "he was decidedly at issue with the company upon some points relative to the inquiry"].

The Coroner said that, on the opening of the inquest, he had at once considered that it was a case which ought to be adjourned, in order that the jury might have the assistance of some of the surveyors from the Board of Trade. He had accordingly communicated with the Board of Trade, and received a letter in reply the previous day which stated that it was impossible that Captain Robertson, the Surveyor-General, could attend the inquiry before Saturday next. He, therefore, thought that, under those circumstances, it would be most advisable that the jury should have the benefit of the experience of those officers, and, with their permission, he would adjourn further proceedings till Saturday morning at nine o'clock. He (the Coroner) trusted that both the company and Mr. Scott Russell would be ready on that occasion with any evidence which could throw the smallest light upon the causes which had led to so disastrous an accident.

One of the jury said that they hoped every effort would be made to discover the man who had turned off the cock or valve which led from the stand-pipe into the stokehole.

Mr. Scott Russell said it would be proved by witnesses that the cock of the valve was open on Tuesday, and when the vessel left the river on Wednesday.

Mr. Leverson intimated that the company were in no degree responsible for what had taken place, and the evidence adduced had established

this on the company's behalf. He had no desire to call further evidence unless wished for by the court.

The Coroner said it was most likely the jury would like to examine Mr. McLennan the chief engineer.

The inquiry was then adjourned till Saturday morning.

The Special Correspondent of the *Times*, who is now at Weymouth, states that "the repair of the damages inflicted by the explosion has already commenced, Mr. Scott Russell having contracted to restore the whole for 5,000*l*. If it should turn out that either of the forward boilers has been injured, 5,000*l*. will hardly suffice for the entire restoration. From the fact of there having been no escape of steam from either of the boilers at the time of the explosion, when there was a pressure on each of 22*lb*., it is believed that they have escaped without material injury. The mere joinery of the cabin fittings and the redecoration of the grand saloon can, and doubtless will, soon be completed. With the ironwork, however, it is a different affair. All this must be executed in London from the working drawings of the vessel, and sent down piecemeal by rail to Weymouth, where it can be bolted together on board the ship. Mr. Scott Russell's contract is to finish the whole ship in her former state as she left the river within three weeks."

HOW TO MAKE A RIFLE BARREL.

THE barrel of a rifle when turned and bored to its finished dimensions is so different a thing from what it was originally in the hands of the smith that its intermediate stages of manufacture may well be described. The problem which has to be solved by the workers at Enfield, and other places which contract with that vast establishment is, how to convert plates of the finest Wedgebury iron, 13 inches long, 9-16 inches thick, and having bevelled edges, which make the sides vary in width from 5½ in. to 5 in. respectively, into a slight but strong tube capable of withstanding the shock within it of innumerable discharges of gunpowder, and of directing unerringly a bullet of lead to a mark 1,000 yards distant from its muzzle.

The plate or "skelp" of iron intended for conversion into a barrel has, in the first instance, an almost white heat given to it, and is then passed between a pair of corrugated rolls, the upper roll having semi-circular projections running latitudinally around it, and which fit flutings sunk into the lower roll. The effect of this pinching is to bend the barrel plate longitudinally. It is next passed between double flutings on the same rolls, and this operation makes a cylinder of the "skelp," minus the welding. The bevelled edges are made, however, to approach each other for this purpose, and welding is the next process. A rod or mandril of iron about ¾ the in. diam. is passed through the orifice of the "skelp," and it is then placed in a reverberatory furnace. When sufficiently hot for the purpose, it is taken to the rolls for welding and drawing out to length and shape. These rolls and their framings resemble much those ordinarily used for rolling iron. There is, however, an important difference—the grooves or flutings upon them are turned out eccentrically with the axis of the rolls. This is for giving the requisite taper from muzzle to breech of the barrel. When the heat is sufficient, which of course practice enables the workman to decide, the barrel is withdrawn by aid of the mandril from the furnace, and laid on an iron rest in front of the mill. The operator now watches carefully his opportunity to thrust it into one of the grooves of the running rolls at a moment when they are prepared to administer the proper pinch for tapering the barrel. A series of these grooves, each smaller than the other, now receives the gradually welding and elongating barrel, until the gauged recess in the rolls finishes the rolling process. In this last time of passing between the rolls the mandril is turned round differently, and

a guard attached to it coming in contact with the rest, a boy stationed at the back of the rolls receives in a pair of tongs the barrel only, the mandril remaining behind for another operation. This boy, whilst the heat is still upon the barrel, roughly straightens it upon an iron surface. After this it is placed under a power press provided with beds or swedges of the same length as the barrel, the lower of which is horizontal and stationary, and the upper one rising and falling by means of a central joint, which allows it to "give" to any irregularities. Supposing all to be sound and satisfactory so far, the next operation will be that of "lumping," or having the cone seat welded on. This is rather peculiar, and demands especial observation. A nice heat is taken on the breech end, and a piece of iron of sufficient dimensions is put on the particular place where it is needed by hand. Then another heat is taken on all together, and whilst in a soft state a mandril is driven into the breech end. It is next placed between dies of the form required, and repeated blows from a trip hammer brings the cone to its proper shape.

This machine is of American invention, and it is very effective. Its principal parts are of wood. The hammer itself, or lever, is hung on journals, the end carrying the die being by far the heaviest. A disc, fitted with a number of studs on its outward diameter, lies at right angles with the other end of the lever. The disc revolving rapidly, and fitted with a fast and loose pulley for disengaging, &c., carries with it the triangularly-formed studs—of which, indeed, there are 12 of about 4 inches in length, and they strike the end of the hammer lever. It is needless to say that the hammer itself, therefore, rises and falls, rapidly, too, on the principle of the tilt hammer. In fact, at Enfield this hammer, with its die face—so to speak—falls upon the cone seat of a rifle barrel at the rate of 300 times per minute. Annealing is the next thing to be done, and it must be done carefully. The atmosphere must be jealously excluded, and charcoal used to prevent decarbonisation. Great care is necessary with regard to the degree of heat applied in annealing. The desideratum is to make the material "mild" and easy to work without deteriorating its strength or quality.

The succeeding process is that of rough boring. This, too, is accomplished at the Government works in a machine of American origin. The machine is so contrived as to bore four barrels at once. Perhaps a brief description of it may not be uninteresting. Four spindles, geared together, are driven by a pulley with a loose one beside it. These spindles rest horizontally on a frame supported by two standards, the frame also forming a trough, and holding an abundant supply of cold water for keeping the barrels cool whilst being bored. The boring "bits" resemble twisted augers, the cutting portions being about six inches in length, but welded to rods sufficiently long to pass completely through the barrel. The ends of these bits are secured into the sockets of the spindles, the barrels being fastened horizontally in the machine. A self-acting feed causes the bits when in motion to take a cut completely through the barrels. The operation is repeated, and then the barrels are taken out and straightened by blow of hammer. The outside of the barrel next claims attention, and it is turned in a peculiarly constructed self-acting slide lathe, with a copying bar attached to produce the required figure. The tool rest of this machine is so devised as to carry two cutters, one in front, the other opposite and behind. One of these is to "rough," whilst the other takes a light and smooth cut. In order to prevent chattering a very solid bearing is made to follow the cutters closely. The turning properly done, another boring becomes necessary—the all-important one. Now one barrel at a time only is operated upon, the machine being a horizontal one fitted with a bracket which fits the barrel on the outside. The "bits" used for this boring are square, the sides being carefully ground on a stone. It does seem strange that so simple an instrument—by the aid only of the truthful eye of

a workman—should be sufficient for the purpose of making an accurately parallel hole through a rifle barrel; but it is so. One end of the square bit fits a socket, and is made to revolve to the tune of something like 300 revolutions per minute. On two sides of the squares of the bits strips of deal wood are placed, and it is astonishing to note the perfect truthfulness attainable by these primitive means. Of course the gauge is put in requisition when this boring, for which oil is the lubricator, is completed.

The chamber at the breech-end is next attended to, and a rose-faced pin-drill is the implement used for boring it out. Afterwards the breech-pin is secured to it, and then the proving is commenced. The inspector, whose duty is momentous, at this stage, too, steps in and examines every part of the workmanship and material. Passing this ordeal, the barrels are now ground on an ordinary grindstone to a gauge. Sundry operations follow, the lump or cone seating is shaped up by a cutter, and brought nearly to a finish—the breech-pin is also now brought into form by similar means. Indeed, revolving cutters or "mills" are the universal tools at Enfield, whilst the variety of names given to them for identification is amusing.

The barrels are next drilled and tapped to receive the nipple, then clamp-milled about four inches up from the middle, and on each side of the foresight, so that the bayonet may fit well. The barrels are now drawfiled from end to end. Gauges are next applied once more to every part, and the rifling must be performed.

The machines used at Enfield for cutting the three rifle grooves in each barrel are of Belgian manufacture, strange to say, most of them having come from Liège. To describe them without diagrams is difficult. Their beds resemble somewhat those of the ordinary slide-lathe. On each bed there is a slide working backwards and forwards, after the plan, almost, of a planing machine. This slide is provided with a pinion which gears into a rack, the end of which slides on a radial bar set at the required angle from the central line of the machine. As the slide is made to traverse slowly along the bed, the radial bar is made to advance or recede according to the direction in which the slide is going, and of course gives a gentle twist to the pinion which has the cutter bar attached. This latter requires some explanation. It is composed of a bar of steel passing clear through the barrel, and filling it. The end remotest from that fixed in the pinion of the slide has a kind of mortice cut in it, with an inclined plane acting against a similar one on the other. The incline on the cutter has the point of a fine threaded screw bearing against it. This screw is prevented from moving by a square rod into which it is fixed, and which slides through a disc at the extreme end of the machine. All the time the cutter is travelling, it leaves the screw, and, as a spiral spring now acts upon the end of the cutter opposite the inclined plane, the tendency must be to force it out, and make it wider at the breech-end to the extent mentioned in a former article of this Magazine (September 2nd). The cut commences at the muzzle, and the barrel is firmly clamped whilst the "rifling" is going on. At the breech-end there is an arrangement for setting the barrel into proper position for cutting the grooves at equal distances from each other. Supposing the spiral grooves or rifles to be now cut in a barrel, the next operation will be to remove the slight "burr" which the cutter, however clean it may have cut, will have inevitably left in its progress from muzzle to breech. In order to accomplish this the barrel is placed so that it cannot turn round, though it may be moved laterally. A leaden "lap" made to revolve at a very rapid rate is now introduced, and the barrel is made to slide to and fro upon the lap. The effect is to remove every vestige of wire edge which the cutter may have left, and to polish the interior of the barrel like a mirror.

Released from this machine, the barrel is next taken to the proof-house, where possibly the explosion within it of a heavy charge of gun-

powder, and the propulsion through it of a bullet, may reveal some defect which will condemn it. If, on the contrary, it stands this test, it is passed forward to the machine or revolving cutter, which "mills" the fore-sight into shape. A little hand labour—such as removing by aid of smooth files any trifling imperfections left by the various machines—is now performed, and then comes the task of fixing the all-important "back-sight." This must be most carefully done, for accuracy of range and aim depends on this. The V, which is the centre point of this sight, must range exactly with the centre of the fore-sight, and both be central with the centre of the axis of the bore of the barrel. Without attending scrupulously to these points, indeed, the whole of the previous labour might be deemed as thrown away. Presuming that all has been satisfactorily done, from the bending of the "skelp" to the attaching of the back-sight, and that inspectors have pronounced it very good, the barrel has next to be bronzed; and in order to effect this, the exterior is made, in the first instance, to become oxidised, by application of water, and then to pass through a simple chemical process. Polished over the bronzing, it is now fit for its walnut-wood bed, and for the companionship of those component parts which go to make up the handsome weapon with which the various and happily increasing number of rifle club members are becoming familiar, but which we trust they may not be called upon to use hostilely. For much of the information in the foregoing paper we are indebted to the courtesy of C. F. Hayes, Esq., of the Small Arms Factory, Enfield.

INSTITUTION OF MECHANICAL ENGINEERS.

THE Annual Meeting of this body was held in Leeds, during last week, under the presidency of Mr. John Penn, of Greenwich. The first meeting was held in the Civil Court, at the Town Hall, on Tuesday, Mr. Penn presiding.

FILE-CUTTING MACHINERY.

The first paper was a description of Bernot's file-cutting machine, by Mr. Thomas Greenwood, of the firm of Greenwood and Batley, machine makers, Leeds. Mr. Greenwood alluded to the fact that whilst machinery had been introduced into most manual operations, file-cutting remained stationary. Various machines had been invented in America and this country, and large sums of money had been spent by manufacturers in Sheffield, but partly from difficulties, real and imaginary, and also from the opposition of the operative file-cutters, these experiments had failed up to within a recent period. So great were the prejudices of the operative file-cutters that they refused to teach the apprentices how to grind their cutting chisels until the last year of their apprenticeship, and the tariff of prices remain fixed, on the supposition that no improvement had taken place in the rolling of steel, thus entirely ignoring the progress that had been made; and forgers charged the same price for drawing the tang upon a round or square rod of steel for a parallel or equalling file as they did for forging a half-round taper file of the same length. The actual process of file-cutting, however, was one of the simplest description. It consisted in driving a chisel of suitable form and inclination to a small depth into the prepared surface of the blank, and steadily withdrawing it again. The difficulties to be surmounted were to present the blank perfectly parallel to the cutting edge of the chisel; to withdraw the chisel from the incision made in the blank without damaging the edge of the newly-raised tooth; to prevent a rebound of the chisel after the blow which drove the chisel into the blank before the next blow was struck; to give a uniform traversing motion to the blank, ensuring regularity in the teeth; to proportion the intensity of the blow to the varying width of the file, so as to give a uniform depth of cut; and to perform these operations at such a speed as to make them commercially pro-

stable. In most of the attempts which had been made the idea had been to construct an iron arm and hand to hold the chisel, and an iron hammer to strike the blow, but the vibration which attended this mode caused irregularity in the work, and a ragged uneven edge on the tooth. The slow speed, too, at which these machines were worked rendered them unable to compete with hand labour. In the machine invented by M. Bernot, of Paris, these difficulties were obviated. The blow was given by the pressure of a flat steel spring pressing upon the top of a vertical slide, at the lower end of which the chisel is firmly fixed. The slide was actuated by a cam, making about one thousand revolutions per minute, thus obviating the vibration consequent upon the blow with an iron-mounted hammer. After explaining the machine more minutely, by means of diagrams, Mr. Greenwood remarked, with regard to the durability of the cutting chisels, that it was found that they cut five times as many files as could be cut by hand, without re-sharpening. In the files cut by this machine the teeth were raised with perfect regularity, and, consequently, when the file was used, each tooth performed its proper share of work; whereas, in hand-cutting, from the varying power of the muscles, especially towards the close of the day, it was impossible to produce such perfectly uniform work. Every description of round or half-round files was cut by the use of a revolving bed, and dividing apparatus for round and hand round files. The paper concluded by stating that a manufactory employing twelve of these machines had been established at Douai, in the north of France, and another at Brussels. A machine, which had been fitted up in the room, was then put into operation by means of manual power, which, however, could not give the full velocity, but notwithstanding this the work done was of a very satisfactory character, the files cut being the full-sized flat hand files. A discussion ensued, and in reply to Mr. Fothergill, Mr. Cowper, and others, Mr. Greenwood said that the relative cost of cutting the files, as shown by practice at Douai, was as 4d. per dozen to 2s. 8d. for manual labour, on a certain class of work, which left a large margin after the cost of the machine and power in favour of machine work. As to the durability of the files, it was decidedly greater than that of ordinary files. The difference of production was as ten to one, and the machine would last as long as ordinary complicated machinery. There was no difficulty in cutting round and half-round files. There was also an additional advantage in the equality of the work obtained. In hand labour it was found that the files made in the afternoon were not so good as those made in the morning, the muscles becoming relaxed, and the blow, therefore, less regular in force. It cut the taper files all one depth, but no doubt the pitch could be altered if necessary, by making the machine a little more complicated. On the suggestion of Mr. Maudslay, Mr. Greaves, who had charge of the machine, briefly addressed the meeting. He said that he had been engaged in file-cutting twenty-five years, and he was prepared to state that the machine would cut as good files as could be made by hand, if properly attended to. It was necessary, however, that the machine should be fixed, and not re-set every half-hour. The President then thanked Mr. Greenwood for his paper, and the discussion terminated.

ECONOMY AND DURABILITY OF STEAM-BOILERS.

The Secretary then read a paper by Mr. Longridge, of Manchester, on the "Economy and Durability of some classes of Steam-boilers." The paper was of a very elaborate character, requiring a number of statistics and diagrams for its illustration. With respect to the best surfaces for heating, Mr. Longridge said there could be no question that horizontal surfaces were the best for absorbing heat, but unless this heat were carried off, and accumulation prevented, the practical value of such surface for generating steam would be much impaired, and the plates speedily injured. Hence those surfaces were to be pre-

ferred which, combined with naturally good positions for absorbing heat, offered the greatest facility for circulation of the water. The paper concluded by remarking that great as had been the progress of late years in the construction of steam-engines, and the economical use of steam by working expansively, this had not been accompanied by equal progress in the construction of steam boilers; for, whatever might be the scientific knowledge in the latter branch of engineering, it was certainly not favourably exhibited in the generality of boilers in present use. On the contrary, the laws of combustion and evaporation seemed generally to have been almost entirely ignored, and waste of fuel and rapid deterioration of boilers had been the natural consequences.—Mr. Kitson briefly alluded to the importance of the subject raised by Mr. Longridge, and said that the time had come when more attention ought to be paid to the construction of their boilers. One great mistake which had hitherto been committed was, that persons purchasing boilers simply fixed the power and the amount per ton, without reference to the construction. This had, commercially, been really a great error, because if greater power were given to the boiler-maker, and a higher degree of intelligence brought to bear on the construction of boilers, the result would be to the benefit of the purchaser.—After some remarks from Mr. Goodfellow, of Manchester, with respect to evaporation, the President and Mr. Bastow made a few observations, and the discussion closed.—A vote of thanks was then passed to Mr. Longridge.

MORRISON'S DIRECT-ACTING STEAM CRANE.

The secretary then read an interesting paper by Mr. Morrison, of Newcastle-on-Tyne, descriptive of a direct-acting steam crane invented by that gentleman. For the usual complications of ordinary steam cranes, there was in this crane substituted a piston with a flexible piston-rod, working steam-tight through a stuffing-box in the top of the crane-post, passing over two pulleys, and forming the chain. By this arrangement the different movements of the crane were performed with the greatest facility and precision, the lifting being performed by the admission of the steam above, the piston forcing it down the cylinder or crane post to a distance equal to the lift required. It would lift 32 feet, swing round, discharge, and swing back to re-load, three times per minute. In other words, it would discharge three tubs of coal, of 2 tons each, in one minute. Comparing it with water, taking the latter at a pressure of 60 lbs. per square inch, and steam at 50 lbs., the writer said he had found that the cost of steam was but 4½d. per hour, whilst water would be 8d. The cost of a machine with boiler and steam-pump would be about 460l.—Some discussion took place with respect to the relative cost of hydraulic and steam cranes, after which a vote of thanks was passed to Mr. Morrison.

ALLAN'S NEW PRESSURE GAUGE.

The next paper read by the Secretary was one by Mr. Alexander Allan, on a new pressure gauge, invented by him. The principle of the gauge consisted in indicating pressure, either above or below that of the atmosphere, by the more or less compressed or expanded condition of a measured quantity of air contained within the gauge. This was acted upon by the pressure through water or other fluid contained within a bent pipe, which was attached at one end to the gauge, and at the other to the boiler or vessel containing the pressure to be indicated. The surface line of the water, as seen in a glass tube attached to the body of the gauge, indicated the extent of the pressure, on a graduated scale.—Several gentlemen expressed their favourable opinion of this gauge, one of which was exhibited, and a vote of thanks was passed to Mr. Allan for his paper.

HASTE'S SAFETY-VALVE.

The last paper read was one by Mr. William Naylor, of London, descriptive of Haste's safety-valve for steam-boilers, which was illustrated by a section of the valve, and a number of diagrams.

We cannot give a description of the valve without diagrams, but we may state that the objects of the invention are to carry off the steam as fast as it is generated above the pressure the boiler is intended to work at; to be entirely out of the reach or control of any one to tamper with or overload it; and to be so arranged that in the event of the water getting low in the boiler, the valve shall blow off steam, and avoid the possibility of any explosion or injury beyond the burning of the plates if more water be not supplied.

A vote of thanks was accorded to Mr. Naylor, and the sitting terminated, the members proceeding to visit Messrs. Marshall's flax-mill, and other works thrown open to their inspection. In the evening of Tuesday a *conversazione* was held in the Victoria Hall.

The Second Meeting was held in the Civil Court on Wednesday. Mr. Penn again presided.

SUPER-HEATING OF STEAM.

The first paper read by the Secretary was "On the Application of Super-heated Steam in Marine Engines," by Mr. J. Penn, the President. The paper was of a technical character, but of great interest to practical men. The writer stated that an opinion in favour of super-heating the steam supplied to steam-engines had long existed, and it had been maintained that important advantages might be obtained from this principle, though until recently but little had been effected in its practical application. Super-heated steam seemed to have been first definitely tried by Mr. Thomas Howard, of Rotherhithe, about twenty-seven years ago. Considerable economy was effected, but the machine was too delicate in its construction to test the experiment properly (though it established the principle), and it was given up. Soon afterwards Dr. Haycroft, of Greenwich, took up the subject, and was convinced of its advantages. The importance of the principle was first impressed upon the writer many years ago, and he became satisfied, from the results of experiment and observation, that great advantages in economy of fuel might be obtained, the main question to be settled being whether it involved any serious practical objection from complication of apparatus, risk of derangement and failure, or difficulty in lubrication of the engine. Recent trials, made on a large scale, led the writer to the following conclusions:—That an advantage can be obtained from the use of super-heated steam, amounting to an economy of fuel of from 20 to 30 per cent. in marine engines; that a moderate extent of super-heating enables all the important advantages of the plan to be obtained; and that apparently nothing objectionable is then necessarily involved from extra wear and tear, risk of failure, complication of apparatus, or difficulty in lubrication. The real advantage in employing super-heating steam appeared to be in preventing the presence of any water in the cylinder of the engine, and ensuring that it should be occupied always by nothing but pure steam; making it a real steam-engine, instead of one working with a mixture of water and steam. In all condensing engines the interior of the cylinder, being open to the condenser during half the time of each revolution of the crank, was exposed during that time to the low temperature of the condenser, or about 125 degrees, with a vacuum of 13½ lbs. per inch below the atmosphere, or 27 inches of mercury. There was, consequently, a rapid absorption and radiation of heat from both the sides and the end of the cylinder, thus cooling down the whole mass of metal. The steam admitted into the cylinder in the next stroke, at a temperature of 260 degrees at 20 lbs. per inch above the atmosphere, coming in contact with these cooled surfaces, heated them up again, being robbed thereby of a portion of its heat; and the consequence was the deposit of a quantity of water in the cylinder, from the condensation of an amount of steam proportionate to the quantity of heat imparted to the metal of the cylinder. A portion of this water in the cylinder might be evaporated again into steam towards the end of the stroke, by carrying the

expansion of the steam down to a sufficiently low pressure: but even then its effective value as steam in propelling the piston would have been lost during all the previous position of the stroke. Now, if as much heat be added to the steam, by super-heating it before entering the cylinder, as would supply the amount of which it was robbed by the cylinder, it would remain perfectly dry steam throughout its stroke, and not a drop of water would be deposited. This, the writer believed, was the mode in which the super-heating of steam acted in producing a saving of steam, and consequent economy of fuel, by preventing the extensive loss or waste of steam that ordinarily took place. The addition of 100 degs. of heat to the temperature of the steam insured the accomplishment of the desired object with steam at 20 lbs. per inch, as used in marine engines. The writer then proceeded into more technical details, reference being frequently made to the diagrams, and said, that having fitted the engines of the Peninsular and Oriental Company's steamer *Valetta* with super-heating apparatus (illustrated by diagrams), the experiments made gave a saving of 20 per cent. of fuel. These experiments were not complete, but they were entirely satisfactory as far as they went.—A very interesting though technical discussion ensued, in which Mr. W. S. Ward, Mr. Morrison, Mr. Cowper, Mr. Maudslay, the President, and other gentlemen, took part; after which a vote of thanks was passed to the President for his paper.

SUPPLYING LOCOMOTIVE TENDERS WITH WATER.

The Secretary read a "Description of Fryer's Apparatus for Supplying Locomotive Tenders with water," by Mr. James Fenton, of Low Moor. By this apparatus it is proposed to force water from tanks below the level of the lines into the tenders, by means of the pressure of condensed steam from the engines; and it was stated that the experiments tried in a large sugar manufactory at Manchester had been highly successful. The great value of the apparatus was where water could only be obtained at low levels, and it was said that there was greater protection from frost, the water being stored below the level of the ground. After a short discussion, in which Mr. Fryer explained the apparatus in a more popular manner, a vote of thanks was passed to Mr. Fenton for his paper, and to Mr. Fryer for his communication.

CONSTRUCTION OF STEAM BOILERS.

The Secretary then read a communication from Mr. B. Goodfellow, Hyde, "On the Construction of Steam Boilers."

IMPROVED RAILWAY BREAK.

The next paper read was by Mr. Alex. Allan, "On Increased Railway Break Power for Stopping Railway Trains." After referring to the importance of increasing the break power for stopping fast trains within a shorter distance than at present, the writer said that the subject of the paper was a plan for obtaining increased break power, by retarding the speed of the engine, by means of a throttle valve, placed in the exhaust pipe, which could be instantly closed to any required extent, so as to obstruct the exit of the steam from the cylinders, the regulator remaining open, at the same time that the exhaust steam was admitted to a small cylinder, the piston of which acted through levers on a break on the engine wheels. The break cylinder applied the breaks simultaneously to the leading and trailing wheels of the engine, and the driving wheels were at the same time retarded by the back pressure of the exhaust steam on the pistons, consequent upon the closing of the throttle valve in the exhaust pipe. The power of the break cylinder was limited, so as not to skid the wheels, in order to avoid wearing flat places on the tyres, and to produce the greatest effect in retarding the speed. A break power of from 14 to 22 tons could thus be obtained by the steam break alone. The retarding power of this steam break had been tried on the Scottish Central Railway with the most satisfactory results. A train consisting of engine, ten-

der, and 11 empty carriages, weighing 85 tons, and going at a speed of 36 miles per hour, was stopped in 23 seconds, running 220 yards. In reply to an inquiry, Mr. Allan said the application of the break was so regulated as to prevent any shock.

STEAM CRANE.

The Secretary next read "A Description of a Steam Crane," by Mr. J. C. Evans, of London, which gave rise to some remarks by Mr. Maudslay, the President, and others, after which the President thanked Mr. Evans for his paper.

THE PUMPING-ENGINES AT ARTHINGTON.

The proceedings of the sitting were closed by a description of the pumping-engines at Arthington Water-works, communicated through the Secretary, but it contained no facts which have not already been made public.—Mr. Anderson then moved a vote of thanks to the President for his conduct in the chair, which was seconded by Mr. Fothergill, and carried by acclamation. At the close of the meeting the following objects of interest were exhibited for the inspection of the members:—A steam carriage for common roads at the works of Messrs. Witham, Kirkstall-road; Naylor's steam-hammer, Kirkstall Forge; two locomotive engines, with welded boilers, at the Midland Station; Aytoun's safety miners' cage, in a yard opposite to the Town Hall; roof and large bell of the Town Hall; Hattersley's type-composing machine, in the Victoria Hall; and Mr. James's machine for winding up clock weights, in the entrance to the Victoria Hall. The Members were taken by special train to the pumping-works at Arthington, after which they dined together in the Wellington Hall. On Thursday they visited Low Moor and Saltaire.

THE BRITISH ASSOCIATION.

ABERDEEN, WEDNESDAY, Sept. 14.

THE meeting of the British Association for 1859 commenced this evening in the new Music-hall. There was a very large attendance, and great interest attached to the meeting in consequence of his Royal Highness the Prince Consort being the president elect.

Professor Owen, on retiring from the chair, congratulated the members on the prosperous condition of the Association, and that it was presided over by his Royal Highness.

The Prince Consort, after taking the chair, delivered a very able address, which occupied 40 minutes in delivery, and was loudly applauded throughout.

Sir Benjamin Brodie moved, and the Lord Provost of Aberdeen seconded, a vote of thanks to his Royal Highness, which was enthusiastically passed by the large audience.

FLEET-STREET, THURSDAY AFTERNOON, Sept. 15.

We confidently expected to receive a report of the Prince Consort's speech from our correspondent in Aberdeen, in time for publication in this number; but it has not yet reached us, and as we have to publish at noon to-morrow, it is not possible to delay our Magazine further for it.

LIST OF NEW BOOKS.

Brown's Companion to the New Rifle Musket, 2nd edit., 2s. 6d.
Burnett's Tillage a Substitute for Manure, 5s.
English Cyclopædia, Knight's Arts and Sciences, Vol. II., 12s.
Grantham on Iron-ship Building, with vol. of Plates, 2nd ed., 25s.
Laurie's Tables of Simple Interest from 2½ to 5 per cent., 24 edit., 21s.
Moor's The Ventilation of Mines, 5s.
Todhunter's Spherical Trigonometry for Colleges and Schools, 4s. 6d.

THE GREAT EASTERN.—*Erratum*.—For the correction of an error in our last week's article on this ship, see the first paragraph of our "Gossip" of this week.

ON THE EARTH'S INTERNAL TEMPERATURE, AND THE THICKNESS OF ITS SOLID CRUST.

By WILLIAM HOPKINS, Esq., M.A., LL.D., F.R.S.*

IF we descend beneath the surface of the earth, and observe the temperature at different depths, it is found that within a depth ranging from 50 to 80 feet, the temperature changes periodically, being affected to that depth by the heat which the earth receives from the sun at different seasons of the year. The annual variation, however, becomes less as the depth increases, till at the depth above-mentioned it becomes insensible. At greater depths, the temperature is invariable at each point, but increases with the depth, at the rate on an average of 1° (F.) for a depth of between 60 and 70 feet. The best observations which have been made on this subject are those in deep mining shafts and deep artesian wells; the greater depth the more completely do anomalous influences counterbalance each other. The greatest depths at which such observations have been made in Western Europe, are at Monkwearmouth and Dukinfield, in this country; the Puit de Grenelle, at Paris; Mondorff, in the Duchy of Luxembourg; New Seltzerwerk, in Westphalia; and at Geneva. At the first two places the observations were made in vertical shafts of coal mines; the depth of the one at Monkwearmouth being upwards of 1,800 feet, and that at Dunkinfield upwards of 2,000 feet; and in both cases the observations were made while the workmen were sinking the shafts, and with every precaution against the influence of any extraneous causes which might affect the observations. The former gave an increase of 1° (F.) for every 60 feet of depth, the latter for about every 72 or 73 feet. The sinking of the Puit de Grenelle was superintended by Arago. The mean increase of temperature was 1° for every 60 feet. At Mondorff the bore was 2,400, being that of an artesian well; the increase was 1° for 57 feet. At New Seltzerwerk the artesian well, penetrating to the depth of 2,100 feet, giving an increase of 1° (F.) for 55 feet. The average of these is very nearly 1° for 60 feet. Numerous other observations are confirmatory of those results, though observations at smaller depths present many anomalies indicating the operation of local causes.

If a sphere of very large dimensions, like the earth, were heated in any degree and in any manner, and were left to cool in surrounding space, it is shown, by accurate investigation, that after a sufficient and very great length of time, the law according to which the temperature would increase in descending beneath the earth's surface, within depths small compared with the earth's radius, would be—that the increase of temperature would be proportional to the increase of depth. This coincides with the observed law, if we neglect the anomalous irregular variations which are found to exist more or less in each locality. Now according to this law, the temperature at the depth of 60 or 70 miles would probably be sufficient to reduce to a state of fusion nearly all the materials which constitute the earth's external solid envelope; and hence it has been concluded, that the earth probably consists of a central molten mass as a fluid nucleus, and an external solid shell, of not more than 60 or 70 miles in thickness: and some geologists, desirous of rendering the conclusion the foundation of certain theories, have considered the thickness even less than that now mentioned.

This conclusion, however, rests on reasoning in which an important element is wanting. It involves the hypothesis that the *conductive power* of the rocks which constitute the lower portions of the earth's crust, is the same as that of the rocks which form its upper portion. This conductive power of any substance measures the facility with which heat is transmitted through it; and it is easily proved, by accurate investigation, that when the same quantity of heat passes through superimposed strata of different conduc-

* Authorised abstract of a recent lecture at the Royal Institution.

tive powers, the increase of depth corresponding to a given increase of temperature (as 1°), is in any stratum proportional to the conductive power. Consequently, if the conductive power of the lower portions of the earth's solid crust be greater than that of the thin upper portion of it through which man has been able to penetrate, the depth to which we must proceed to arrive at a certain temperature (as that of fusion for the lower rocks) will be proportionally greater. The precise nature of the rocks situated at a great depth can only be judged of by analogy with those which are accessible to us; but those geologists who adopt the conclusion of the extreme thinness of the earth's crust, will doubtless admit that its inferior part must be of igneous origin, and must therefore be allowed to bear a certain resemblance to igneous rocks on the surface of the earth. Mr. Hopkins had recently made a great number of experiments on the conductive powers of various rocks. That of the softer sedimentary rocks, which are great absorbents of water, is very much increased by the quantity of moisture they contain; but taking chalk, one of the best absorbents, its conductive power, even when saturated, is not half so great as that of some of the igneous rocks on which Mr. Hopkins had experimented. Calcareous, argillaceous, and siliceous substances reduced to fine powder, stand, with reference to their conductive powers, in the order in which they are now mentioned, the conductivity of the first being the least; and when in a compact state, all that contributes to give a hard and crystalline character to the substance, and continuity to the mass through which the heat is conducted, increases the conductive power. These considerations lead to the conclusion that the conductivity of the inferior portions of the earth's solid crust must be much greater, and may be very much greater, than that of the less consolidated and mere superficial sedimentary beds. Moreover, the temperature of fusion of certain substances, as Mr. Hopkins had shown by experiment, is much increased by great pressure; and by analogy it may be concluded, that such would, at least in some considerable degree, be the case with the mineral matter of the earth's crust. The chalk is that formation in which the most numerous and some of the best observations on terrestrial temperatures have been made, and it would seem impossible to conclude from actual experiment and the considerations above stated, that its conductive power can exceed one-third of that of the inferior rocks, and may not improbably be a considerably smaller fraction of it. Now the increase of depth in the chalk corresponding to an increase of 1° (F.) is well ascertained to be very nearly 60 feet, and therefore the rate of increase in the inferior rocks must probably be at least three times as great as in the chalk, and may be very considerably greater still. Hence, supposing that the thickness of the solid crust would be about 60 miles, if the conductive power of its lower portion were equal to that of chalk, its actual thickness must probably be at least about 200 miles, and may be considerably greater, even if we admit no other source of terrestrial heat than the central heat here contemplated.

There is also another way of investigating the thickness of the earth's crust, assuming the whole terrestrial mass to consist of a fluid nucleus, inclosed in a solid envelope. If the earth were accurately spherical, instead of being spheroidal, its axis of rotation would always remain exactly parallel to itself, on the same principle as that on which the gyroscope preserves, in whatever position it may be held, the parallelism of the axis about which it rotates. But the attraction of the sun and moon on the protuberant equatorial portions of the earth's mass causes a progressive change in the position of the earth's axis, by virtue of which the North Pole, or that point in the heavens to which the northern extremity of the earth's axis is directed, instead of being stationary, describes a circle on the surface of the heavenly sphere about a fixed point in it called

the pole of the ecliptic with a radius of nearly $23\frac{1}{2}^{\circ}$, equal to the inclination of the equator to the ecliptic, or the *obliquity*. The whole of this revolution is completed in about 25,000 years; but, as follows from what has just been stated, without any change, beyond small periodical ones, in the obliquity. A corresponding change of position must manifestly take place also in the position of the equinoxes, which have thus a motion along the ecliptic in a direction opposite to that in which the signs of the zodiac are reckoned, completing a revolution in the period above mentioned of 25,000 years. It is called the *precession of the equinoxes*.

This precessional motion has been completely accounted for under the hypothesis of the earth's entire solidity, and that of a certain law according to which the earth's density increases in approaching its centre; but some years ago Mr. Hopkins investigated the problem with the view of ascertaining how far the observed amount of precession might be consistent with the existence of a fluid nucleus. The result was, that such could only be the case provided the thickness of the solid shell were much greater than that which, as above stated, has been supposed by many geologists. The numerical result was, that the least admissible thickness of the crust must be about one-fifth of the earth's radius; but without assigning any great importance to an exact numerical result, Mr. Hopkins had a full confidence in the investigation, as showing that the thickness of the crust could not be so small as 200 or 300 miles, and consequently that no geological theory can be admitted which rests on the hypothesis of the crust being nearly as thin as it has been frequently assumed to be.

The influence of the interior fluidity on the precessional motion above described, is due to the difference between the motions which the attractions of the sun and moon tend to produce on a solid mass in one case, and a fluid mass on the other. It has been recently stated, as an objection to this investigation, that the interior fluid mass of the earth may move in the same manner as if it were solid. The only reply which could be given to such an objection was, Mr. Hopkins conceived, that it was mechanically impossible that these motions should be the same, though the resulting precessional motion for the solid crust, under certain conditions, to be determined only by the complete mathematical solution of the problem, might be the same as if the whole mass were solid. The effect of the attractions of the sun and moon also depends on the ellipticity of the inner surface of the solid shell; and it has been said that since that ellipticity depends on the law of the earth's density, which can only be imperfectly known, no result can be depended on which involves that ellipticity. This was not a correct statement of the problem. It was assumed in the solution referred to, that the ellipticity of the inner surface would depend partly on the law of density, and partly on the forms of the isothermal surfaces. Mr. Hopkins had supposed it possible, at the time he was engaged in this investigation, that a surface of *equal solidity* might approximate to a surface of *equal pressure*; he has now experimental reasons for believing that it must approximate much more nearly to an internal surface of *equal temperature*. Now, for depths greater, probably much greater, than those which have often been supposed to correspond to the thickness of the earth's solid crust, there is no doubt that the internal isothermal surfaces have a greater ellipticity than the external surface itself—a conclusion which is independent of the law of density. Hence, a like conclusion will hold with reference to the internal surface of the shell, if it approximate sufficiently to the surface, of equal temperature; and this is the conclusion most unfavourable to the thin shell supposed by some geologists. Restricting the interpretation, then, of Mr. Hopkins's results to the question, whether the earth's solid shell be as thin as some geologists have supposed, or at least several hundred miles in

thickness? (and this is the only question of geological importance)—Mr. Hopkins denied the validity of either of the objections above stated.

Thus, both the modes of investigation which had been described lead to like conclusions respecting the least thickness which can be assigned to the solid envelope of our globe. It must be much greater than geologists have frequently imagined it to be.

THE NEW CALCUTTA MINT.

THE machinery for the new Calcutta Mint is rapidly approaching completion, and will be shipped for that place before the end of the year. We have no hesitation in saying, after a personal examination of the drawings for the building, and of the various mechanical appliances prepared, or in course of preparation by James Watt and Co., for the establishment, that this new money factory will, when completed, be the most extensive and perfect in the world. The designers of it, it is true, have had the advantage of inspecting all existing mints, and thus the opportunity of improving upon them. They have used that advantage with extraordinary effect, however, and have left apparently little for others to improve upon.

The space of ground upon which the machinery, on reaching India, will be erected is large, and the workshops and offices are in course of rapid construction. Two steam-engines of (we believe) fifty horse-power are intended to give motion to eighteen rolling mills of various sizes, for the breaking down and laminating of silver and gold bars. The rollers of these mills are of chilled cast-iron, the largest being 18 inches in diameter, and the smallest 10 inches. There will be eight cutting-out presses of great productive power, from the peculiarity of their make, and the rate at which they will work. What is called the drawbench will not, as in the British Mint, be used. It is considered that well-finished rolls carefully attended to, will produce work as accurate as that which is turned out by this expensive appliance, and we have little doubt of the fact. Twelve coining-presses, made to vibrate at the rate of 200 strokes per minute, and to produce coins as rapidly, *it is said*, complete the fittings of this mammoth Mint. The presses are to be impelled by compressed air acting upon pistons attached to their fly-arms, and working in iron tubes concentric with the vertical screw-pin to which the die is attached—an arrangement altogether new in money-making machinery, and now, therefore, to be put on its trial, except as experimentally at Soho for the first time. At a further period this remarkable work will obtain further attention at our hands, illustrative as it is of mechanical improvement and the march of civilization.

THE GREAT EASTERN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Will you permit me through the medium of your excellent Magazine to put the following question to those gentlemen who are so very confident as to the perfect safety of the Great Eastern, viz., what will be the effect of and upon that noble vessel when her monster engines are suddenly and severally released from all resistance by the paddle-wheels and screw becoming alternately out of water, as must be the case when she is resting upon and running directly across and through the crests of water of more than 40 feet altitude, or rather, of 80 or 90 feet, including the depth of the trough of the sea between them?

W. H. JAMES, C.E.

September 6th, 1859.

SPILL'S NEW MILL-BANDING.—Numerous readers having written to us for the address of the manufacturers of the new mill-banding described at page 152 of our Magazine for September 2, it may save trouble if we mention the address here; it is, we believe, Messrs. G. Spill and Co., 18 Bread-street, Cheapside, London, E.C.

LAUBEREAU'S PATENT AIR ENGINES.

FIG. 3.

FIG. 4.

FIG. 5.

LAUBEREAU'S PATENT AIR ENGINES.

MR. J. LAUBEREAU, Civil Engineer, of Paris, has just completed a patent for "Improvements in Air Engines."

The invention consists in arrangements of machinery for producing the alternate expansion and contraction of air, and in causing the stroke of a piston to be effected by the expanded air, while the return is effected by the pressure of the atmosphere, aided by a partial vacuum obtained at the back of the piston. The patentee forms a heating chamber with double sides and communication between them, and by preference in the shape of a Π , which is placed in a cylinder or chamber round the upper part of the sides, and at top of which is a chamber for containing cold water or other cooling agent. In the space formed between the sides of the cylinder and the sides of the heating chamber, he places a grooved piston of a Π shape, and forms it of some metal of high-heat conducting power, such as bronze. This piston is so carried that it does not touch the sides of the cylinder nor of the heating chamber, there being space for a thin layer of air between it and them. On the top of this piston he forms a chamber, and fills it with some very bad conductor of heat, such as lampblack, and again places on the top of this chamber a cushion of cotton or other like non-conducting material. The piston chamber and cushion are all attached to a central rod, which works through a stuffing-box in the top of the cylinder and through the water space. The non-conducting chamber is kept from touching the sides of the cylinder, a pipe communicates from the bottom of the cylinder to the working cylinder, in which an ordinary piston is placed, and conveys the air to and from the working cylinder, and that in which the air is expanded and contracted. Connecting rods and other agents are employed so as to give motion to the piston in the expanding and contracting apparatus at the dead points of the working piston.

Fig. 1 is a plan of a single-acting engine complete, and Fig. 2 a sectional elevation. Fig. 3 is a plan of a double-acting engine, the cylinder being removed and one generator shown in section; Fig. 4 is a front elevation partly in section; and Fig. 5 a section of part of a generator relating to an improvement in the means of perfecting the vacuum. The same letters refer to like parts in all the figures. a is the foundation plate; $b b$ are the side frames; $c c$ are the external cases of fire-boxes; $d d$ the fire-box covers; $e e$ the smoke pipes; $f f$ the fire-boxes; $g g$ the hot chambers; $h h$ the cold chambers; $i i$ the travelling caps;

$j j$ the boxes containing non-conducting substances; $k k$ the cushions or pads; $l l$ the travelling cap rods; $m m$ the external cases containing cold water or other cooling agents; n the cylinder; o the piston travelling in the said cylinder; p the piston rod; q the hot-air pipe, the lower extremity of which is in direct communication with the hot-air chamber of one of the generators, and from which it is conducted into the cylinder at the back of the piston; r the clack valve admitting the hot air, but intercepting the return of the cold or contracted air; s the vacuum pipes communicating from the back of the cylinder to the cold or condensing chamber h of the same generator; t the clack valve, allowing the egress of the condensed air; u the box bolted to cylinder bottom, through which the contracted air circulates from the clack valve t to the pipe u ; v the connecting rod; w the main shaft and crank; x the cam plate keyed on shaft w ; y the cam bolted to the plate x ; z the cam plate or box; a the vertical oscillating lever; q the fulcrum point on which the lever oscillates; r the rod connecting the lower extremity of the vertical lever to the lever a ; s double horizontal lever communicating an intermittent reciprocating motion to the travelling caps $i i$; t the fulcrum on which the lever s oscillates; $u u$ wheels attached to the sides of the caps $i i$, and on which they roll in order to diminish the friction; x a hot-air or pressure pipe, the lower extremity of which is in communication with the hot-air chamber of the other generator, and from which it is conducted into the cylinder at the front of the piston; y a clack valve admitting the hot air, but intercepting the return of the cold or contracted air; z vacuum pipes communicating from the front of the cylinders to the cold or condensing chamber h of the same generator, passing through the cooling agent contained in the case j ; a a clack valve allowing the egress of the condensed air; b a box bolted to cylinder cover, through which the contracted air circulates from the clack valve a to the pipes z .

The working of the engine is as follows:—Fire being lighted and the piston in the expanding chamber being drawn up, the cold air is driven out of the upper part of the expanding and contracting cylinder, and simultaneously the air in the space and the bronze piston between the fire-chamber and side of the cylinder become heated, and the air expanding rushes from the expanding chamber into the working cylinder, and drives up the working piston. Immediately before the working piston reaches the top of its stroke, the bronze piston has attained the end of its down stroke, and the air in the upper part of the contracting cylinder having become cool by contact with the cold sides and top thereof, a partial vacuum is formed, and atmospheric air entering through openings in the cover of the working cylinder by the aid of the pressure of the atmosphere aided by the partial vacuum, the return stroke is effected, and so on successively.

FIG. 1.

FIG. 2.

COURT'S PATENT GAS-BURNERS.

MR. J. COURT, gas-fitter, of Brompton-row, Middlesex, has just patented a very simple but useful improvement in those gas-burners which have for their objects the better regulating of the supply of gas to the burner and economy of metal used in the construction. The invention con-

sists in forming a chamber in the nib, and filling, or partially filling, the same with a number of layers of fine wire, wire-gauze, perforated plates, or other porous material, through which the gas passes. The progress of the gas is retarded and its pressure diminished; it also becomes heated in its course through the nib, and more complete combustion, and consequently increased illuminating power, are the results. He forms the chamber either by boring the nib at the bottom of sufficient capacity to receive the layers of wire or other material, and he then inserts a plug (previously drilled through for the passage of the gas) in the bottom of the nib, which presses on the material so placed, and confines it in position. Or the nib is first bored from the top, and after placing the material in it is held there by the tip (which may be of iron, earthen, or glass of the usual union jet or bat's-wing slit). Fig. 1 of the accompanying engravings is a sectional elevation of a nib complete, where the layers of wire gauze *b* are inserted through the top, resting upon a metal ring *c*; the tip *d* may rest on the wire gauze, or the wire gauze may be fixed in position as shown by a hollow tool. Fig. 2 shows a sectional elevation of another form of nib, *a*, *a* is the outer shell in which a cavity *b* is bored, the upper part of which may be filled with wire gauze or perforated plate *c*. One or two metal rings are employed to keep the wire gauze from shifting, and the whole is firmly secured by a screw plug *d*.

THE CORT CASE.

We are glad to find that, in accordance with our announcement made a few weeks since, the Cort case has been taken up by Mr. Cobden, Mr. Fairbairn, and their Lancashire and Yorkshire friends. We find that Mr. Fairbairn's late letter to the *Times* has been made the basis of the new proceedings, for the carrying out of which a committee has been formed comprising Mr. W. Fairbairn, Mr. J. Whitworth, Mr. R. Cobden M.P., Mr. T. Bazley, M.P., Mr. J. A. Turner, M.P., and Ivie Mackie, Esq., Mayor of Manchester. The following statement has been published:—

"The immediate object of this fund is to co-operate with the iron and engineering trades of Great Britain for the support of the Cort family, consisting of a son and three daughters, the youngest of whom is seventy years of age. The inventions of Henry Cort for the manufacture of bar iron have reduced the cost of that most indispensable article, during the last seventy years, 68 per cent., as compared with the previous price of foreign iron. They have for the last twenty-five years greatly economised conveyance and transportation by railway and steam navigation, while the iron wire for telegraph conductors could not be made without the same inventions.

"The total value of cotton goods, thread, and yarn consumed and exported in Great Britain for ten years ending 1856, allowing for waste in spinning, and deducting cost of raw material, according to a table given in the *Encyclopædia Britannica*, vol. xiv., eighth edition, p. 255, amounts to more than £265,000,000 sterling, to pay all other expenses, wages, interest, profits, &c. What, then, must be the aggregate value for the last 68 years, which never could have been realized to the same extent had not the steam engine been made available for the purpose, during the whole of this period, by the inventions of Henry Cort.

"We, the undersigned, strongly recommend this subscription to all who feel as we do, the great value of Henry Cort's inventions, not only to the British nation generally for the last seventy years, out of materials abundant and previously useless in our native land, and by native labour, but more especially as regards the past and future trades of Lancashire and Yorkshire.

(Signed) "IVIE MACKIE, Esq., Mayor.
"RICHARD COBDEN, M.P.
"WILLIAM FAIRBAIRN, F.R.S."

The electric telegraph to Melbourne and Adelaide is in constant use, and affords a remunerative revenue. Indeed, the amount of business transacted has forced on the Government the absolute necessity of a second wire. Wires to Bathurst and to Maitland were in progress, and will shortly convey messages between those important towns and the Australian metropolis.

THE LOSS OF LIFE BY THE WRECK OF THE ALMA.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In your impression of last week you have again done the State a service in directing public attention to the sacrifice of life by the wreck of the *Alma* through the neglect of the most ordinary precautions for its preservation at sea, and in consequence of which some twenty human beings who might be still living have been wantonly hurried into eternity. In doing this you again assert for suffering humanity its right to protection from those whose duty and position in the social scale constitute them its custodians and not its destroyers; and the remedy you suggest of putting captains and officers in charge of ships on their trial for manslaughter is the only one likely to induce a better state of things; for however the recitals of such catastrophes may excite our feelings, this process of reformation is far too tardy; and the stronger power of the law, and its rigid and certain application as you recommend, will be the only check to the constant repetition of such cases as that of the *Alma*. The dread of imprisonment, and the public shame and disgrace that must follow a man through life (who having fulfilled his term will still carry about with him, as it were, his moral ticket-of-leave), stigmatised as he would be under such circumstances as the cause of the death of some of his fellow-creatures through his wanton neglect, must have its weight. Repeatedly, when going down the river with ships "clearing out," have I heard the argument used by pilots to the "men on the look-out," as the most forcible they could advance to make them careful, that "they may be put in prison if any loss of life should happen through their neglect of duty." Already is this law enforced in the factory, the mine, and the railway, and the speedy punishment that follows a guard or overseer when a life is lost through carelessness has materially helped to diminish the aggregate number of casualties. Why should not the same consequences attach to captains and officers in charge of ships? Nor should this criminal responsibility be limited only to them. The Lord Chief Justice Clerk, when life was lost by the foundering of the *Orion*, on the coast of Scotland, summed up in these words: "That any person placed in a situation in which his acts may affect the safety of others must take all precautions to guard against the risk to them from what he is doing; and in the event of loss of life through any device resorted to for the purpose of economy, &c., grave criminal responsibility would arise, as well to the captain who neglected to use all appliances in his power to keep the boats in proper order, as to the proprietor who should fail to have supplied sufficient boats in the first instance, or refused proper allowance to have them maintained."

Now, the *Times* states that twenty minutes elapsed after the *Alma* struck before the first boat was got out and lowered, and then, that as there were no *thowl pins* in it, it was unmanageable, and *twenty lives were lost in consequence*. Now, whose fault was it that no efficient means of instantly lowering the boats was at hand, and no *thowl pins* in the boat when on the water? Nay more, how is it that the very circular of the Board of Trade to which you draw such prominent attention, "No. 61, 1857," and which I now give in *extenso*, was in this very case, as it has always yet been, "a dead letter." That circular directs that life-boats shall carry "*all requisite for use*," and that "surveyors are to refuse delarations in future in cases in which the life-boat is in such a position as not to be ready for use in an emergency, or in which efficient means are not provided for lowering it safely and expeditiously into the water." When such regulations as this are never enforced on owners before the ship sails, by officers specially appointed to see them carried out, and the Board of Trade winks at their neglect of public duty, is it to be wondered at that the captain does not trouble his head about such things as *thowl pins* when he is away at sea; and is it likely that one officer who may be sub-

sequently sent to institute inquiry into the cause of the loss of life that has resulted mainly through the neglect, moreover, of a brother officer to enforce proper regulations for its prevention, and which neglect is openly tolerated at head-quarters; I ask, is it likely that any punishment will follow? Take a case that occurred some time since within sight of our shores. One ship ran into another, and more than twenty minutes elapsed before the disabled one sunk, and seventy people were in consequence drowned (only one boat having been made available in that time); yet a simple comment that "it was a common thing for ships to carry their boats in-board," was all the official notice taken of as wanton an instance of wholesale manslaughter as any that the annals of our criminal records can show. With such a case before us is it to be wondered that the game of death goes bravely on, or that such catastrophes as the *Alma's* happen thousands of miles away at sea, when, under the very eyes of the officers here at home, the causes that lead to them are permitted to continue by the Government in spite of all law and justice?

Other criminals who destroy human life must pay the penalties for their misdeeds, but your owners, your captains, and your officers of ships drown their fellow-creatures by hundreds, and boldly stalk about in broad day-light with no other punishment than the troubles of consciences which have already had no influence whatever in guiding them to the just discharge of their duties to their fellow-men. Death caused by inadvertency, and death caused by violence, is the same in its consequence on its unhappy victims; and the men who murder their captain only bring about a like result with the captain who drowns his crew through wanton neglect of the means that might have saved them in the hour of need. Yet who ever thinks of calling to account the latter, whom the law has already stigmatised as *criminally liable*. Equal justice should meet out equal punishment, and be no respecter of persons. The poor and ignorant seamen soon find out how the majesty of the law is vindicated. The little flies are caught, while the big ones break through its meshes that were never framed for their capture. The blessings of wealth, education, and position in society should teach us to set an example of obedience to the laws of our country, and not how to break them, more especially, where the poor and unprotected are the sufferers. Only let any one who reads this take the trouble to go through our docks and inspect a few ships "ready for sea," he need not be long finding thowl pins out, rudders with irons broken, and no yoke lines, oars anywhere, and boats themselves unfit for use. Instances like these he will find by scores; but one of punishment awarded for death caused through such neglect he must search our naval history in vain to find out.

It is a painful reflection that it should be so; but no regrets will find the remedy. The knowledge that punishment by imprisonment would follow every case of life lost through wanton neglect, affords the only hope of a change for the better; and it is the constant agitation of the subject by the press that can alone urge on justice to use its sword. Mercy in such cases to the guilty is only future death and suffering to the unprotected, for sparing justice breeds iniquity.

If those amongst our rulers who preach philanthropy and the exercise of the higher virtues to benighted niggers, and severe punishment to the wretches who enslave and destroy them, would only throw a few of the crumbs of their surplus benevolence to the poor British seamen and helpless emigrants and passengers, many a home would not now be wanting its mainstay and support; many a widow's heart would have been a stranger to the misery of a disconsolate hearth and its fatherless children; and you, Sirs, and the general press of this country, might happily have at longer intervals to comment on such sad stories as "the loss of life by the wreck of the *Alma*," for the public warning and the public good.

Sept. 6, 1859.

CHARLES CLIFFORD.

THE ARMSTRONG GUN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—While the question of rifled cannon is still being mooted, and our ships of war are likely to be fitted with the Armstrong gun, the idea naturally presents itself as to the comparative merits and demerits of this form of arm when applied to naval warfare. Now, while the advantages of long range and extreme precision are indispensable, the lasting qualities of the material from which the gun is made is no less a matter for serious consideration, and I would ask, How far has it yet been proved that a gun with a barrel of steel, and finely grooved, will resist the erosive action of sea-air and moisture? We all know how soon exposure to sea-air rusts the barrel of a common fowling-piece; and if rust acts rapidly on iron, we know it is still more destructive to steel, and it is a question whether a finely-grooved steel barrel would not soon become so pitted with rust, as to injure the precision of the arm, if not to prevent it from being fired at all. Do there not, I would ask, exist some alloys which, while they would present sufficient hardness to form the core of a rifled gun, would be unaffected by rust? I will mention a fact or two which imply the possibility of such being the case. Every one who has used a soldering iron is aware how, after a time, the copper point which is continually in contact with the solder becomes so hard that the best file will hardly touch it. Another and equally hard alloy may be made from zinc and copper mixed in certain proportions, and another exists into which enters the metal aluminium; and no doubt, with a few experiments, an alloy might be found which would answer the purpose.

Now, if such an alloy could be successfully applied, how great would be the advantage which would accrue, both in respect of cleanliness and in the durability of the arm, while from its easy fusibility it might be run into the wrought-iron case, which would give it strength and solidity.

Hoping that this idea may prove useful and interesting to some of your readers,

I have the honour to remain, Sir,

Your obedient servant,

F. MAXWELL LYTE, F.C.S.

Bagnères de Bigorre, Hautes Pyrénées, Sept. 6, 1859.

CONVERTING CAST-IRON GUNS INTO BREECH-LOADERS.

The following cutting from the *Times* may be taken for what it is worth:—"The difficulty hitherto experienced in converting the ordinary cast-iron guns into breech-loaders has at length been surmounted by Mr. Waryn, the inventor of the new breech-loading percussion cannon, which during some recent trials at Chatham discharged 20 shots per minute, who has just succeeded in attaching a wrought-iron breech to a cast-iron gun, the first attempt of the kind which has, as yet, proved successful. The gun experimented upon consisted of the ordinary cast-iron barrel, weighing about 40lb., which having been rifled, Mr. Waryn attached his breech-loading invention to it; this gun being also fired by percussion, as is the case with Mr. Waryn's ordinary breech-loading cannon. The breech is provided with a lever fixed at the end, which by one movement lubricates the chamber, primes the nipple, and closes the breech. By an exceedingly simple contrivance the breech can be almost instantaneously detached from the other portion of the gun, so that in the case of a sudden surprise by an enemy, these guns can have their breeches removed and be rendered entirely unserviceable. During the trials made at Chatham yesterday to test the newly-finished cannon it was ascertained that with a small charge of gunpowder the shot could be thrown 4,000 yards, or upwards of two miles, while by slightly increasing the charge a range of 5,000 yards was obtained, the gun throwing a shower of balls at the rate of 10 per minute, a rapidity of firing which the inventor is able to maintain as long as the ammunition lasts, the current of air admitted each time the breech is opened preventing the gun becoming heated and

expanding. Mr. Waryn has expressed his readiness to take any ordinary metal or cast-iron gun now in use, and to convert it into a breech-loader which shall be capable of discharging from 10 to 20 shots per minute a distance of at least three miles, the barrel being previously rifled."

Our Weekly Gossip.

WE have to ask the indulgence of our readers for several verbal errors which appeared in our last number, and which they have doubtless corrected for themselves—such, for example, as "great deck" for "giant deck" in the article sent from the Great Eastern, and "Plate 7" for "the engraving" on page 169. In the sentence which precedes the table giving the theoretical speeds of the Great Eastern's paddle and screw, on p. 165, an ambiguous statement also occurs, probably through the hurry in which the letter was despatched. The word "practically" should be "proportionally;" the meaning being that the relations between the revolutions of the paddles and the screw indicated by the table held when the ship was moving freely under her steam. Thus, on looking at the table, it will be seen that eight revolutions of the paddle indicates just over 13 knots of speed, which again correspond to 30 revolutions of the screw; then, it was found in practice that both engines worked well together while the one was making eight, and the other 30 (or nearly 30) revolutions. This is all that was meant. To get the speed of the ship from the table the slip must, of course, be deducted.

Numerous letters written in illustration of the alleged want of proper management in the New Works Department of the Admiralty have reached us. For the most part they involve matters of detail into which we cannot conveniently enter. We print the following as a specimen. It is written by "A Mechanic" from Pembroke Dockyard. He says:—

"Gentlemen,—As another proof of the inefficiency of the New Works Department of the Admiralty alluded to in your number for August, I would refer to the new steam saw-mill building at Pembroke recently completed. The upper room is the joiners' shop, and has a glass roof. The place became so unbearably hot during the summer, and there being no means of ventilation provided, large holes were obliged to be torn in the new end walls to admit a current of air. The merest tyro would not have left such a thing unprovided for in the construction. The Chairman of the Dockyard Committee should be asked how much it cost for spoiled paper and clerk's time employed in re-rewriting letters during his superintendence of Pembroke yard. It was not a trifling item."

We have been favoured with a sight of one of the medals now in process of striking at the Mint, and intended as rewards for the valour displayed by our forces in suppressing the Sepoy insurrection in India. It is a fine work of art. The size of the new Indian medal is precisely that of the well-known Crimean decoration, and, in fact, the obverse—the head of Her Majesty, with the legend *Victoria Regina*—seems to be the product of the identical die used for those too lavishly dispensed discs of silver. The reverse, however, presents a totally different device. The British lion, or a lion, is shown standing in all his natural dignity beside an erect figure of Britannia, who, with an oval quartered shield on her left arm, and a reserve of wreaths in her left hand, is extending her right hand as if in the act of bestowing upon a brave, but, so far as the medal goes, invisible warrior, one of the leafy chaplets. The word *India* surmounts the head of Britannia, who it is really refreshing to see represented on her legs after so long a sitting on our expiring coinage of copper, whilst the dates 1857-1858 placed below the frieze declare the period when the immortal deeds of arms for which the medals are to be awarded were performed. The material of which the medals are composed is fine silver, the weight of each precisely one ounce, and the number to be produced, as we are informed, something like 100,000. May those for whom they are intended long survive to wear them, and if need be, go forth to earn others in the Celestial Empire, where treachery, great as that of Hindostan, seems to exist, and where British prowess must again be displayed. Mr. L. C. Wyon designed—as his name under the frieze denotes—the reverse of the Indian medal; whilst the late W. Wyon was the artist for the obverse.

A model showing how the ground will be laid out in terraces for the garden of the Horticultural Society has just been placed in the South Kensington Museum, at the North-end, near the entrance to the ornamental art-rooms. Between the Kensington-

road and Cromwell-road the ground falls about 40 feet, and using this fact in aid of a general effect, the ground has been divided into three principal levels. The entrances to the gardens will be on the lower level, in Exhibition and Prince Albert's-roads, and the central pathway upwards of 75 feet wide, ascending through terraces to the third great level, will lead to the winter garden. The whole garden will be surrounded by Italian arcades, each of the three levels having arcades of a different character. The upper or north arcade, where the boundary is semi-circular in form, will be a modification of the arcades of the Villa Albani at Rome. The central arcade will be almost wholly of Milanese brickwork, interspersed with terra cotta, majolica, &c., whilst the design for the south arcade has been adapted from the beautiful cloisters of St. John Lateran at Rome. None of these arcades will be less than 20 feet wide and 25 feet high, and they will give a promenade, sheltered from all weathers, more than three-quarters of a mile in length. The arcades and earthworks will be executed by the Commissioners for the Exhibition of 1851, at a cost of £50,000, whilst the laying-out of the gardens and construction of the conservatory or winter garden, will be executed by the Horticultural Society, and will cost about the same sum, the greater part of which has been already raised.

Mr. Lough has completed, says the *Leeds Intelligencer*, a model of the statue of George Stephenson, with its pedestal, the monument intended for Newcastle-on-Tyne. The height of the figure is 7 feet 8 inches; but the actual casting model will measure 10 feet high. The figure is upright, and attired in modern costume, with a plaid crossing the chest from the left shoulder; the right hand, holding a pair of callipers, rests on the breast, and the left on a locomotive engine of very early form. The pedestal intended for the support of this statue presents at its four angles types of the labour necessary to engineering works; these are, accordingly, a navvy, a blacksmith, a pitman, and an engineer.

NOTICES.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to K. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 53 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 317, 343.
BOILERS AND THEIR FURNACES, &c., 369.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 317, 324, 351, 356, 373, 376, 379, 383.
SHIPS AND BOATS, including their fittings, 328, 329, 341, 377, 378, 392, 399.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 327, 353, 381, 389.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 320, 330, 333, 355, 370, 371, 392, 400.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 332, 335, 337, 339, 342, 346, 349, 363, 365, 366, 380, 386, 393, 395, 397, 403, 404, 405.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*
LIGHTING, HEATING, AND VENTILATING, 345, 347, 350, 360, 368.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 321, 334, 340, 364, 385, 390, 398.
METALS, including apparatus for their manufacture. *None.*
CHEMISTRY AND PHOTOGRAPHY, 344.
ELECTRICAL APPARATUS, 329.

WARFARF, 336, 367, 372, 402.
 LETTER PRESS PRINTING &c. *None.*
 MISCELLANEOUS, 315, 316, 319, 322, 323, 325, 326, 331, 338,
 348, 352, 354, 357, 358, 359, 361, 362, 374, 375, 384, 387,
 388, 391, 394, 396, 401.

315. H. GREAVES. "Improvements in the preparation of iron bars, of the various forms or sections used in the construction of sheet-iron structures, and in machinery employed for the same." Dated Feb. 4, 1859.

This consists in punching the rivet-holes required in the various parts of iron structures while the iron is hot, and by means of suitable machinery. *Patent abandoned.*

316. W. THOMPSON. "An improved printing telegraph." Dated Feb. 4, 1859.

The improved manipulator consists of a finger-board containing a certain number of keys or touches which are attached to a corresponding number of straight levers; these are connected with an equal number of small rectangular metallic levers which are placed in a circle round the arbor of the escapement wheel of a common clock train or movement, and directly under a horizontal wheel containing thirty little points which the levers are calculated to push out beyond the circumference of the wheel whenever the keys or touches are acted upon by the operator. The same touch that pushes out the pin corresponding with the letter on the type wheel of the receptor pushes in the pin that is against a fixed post, and stops the instrument each time that the last pin pushed out comes against it, and thus prevents any further action until another letter is made. This double motion of pushing in the preceding pin at the same time you push out another is obtained by an apparatus placed under each of the straight levers. The escapement and pin wheels are on the same arbor, and are put in motion by a common clock train. The receptor is put in motion by two clock trains. *Patent abandoned.*

317. A. ALLAN. "Improvements in locomotive steam engines, in part applicable for retarding and stopping railway trains." Dated Feb. 4, 1859.

This invention is not described apart from the drawings. *Patent completed.*

318. J. W. HART. "Raising water or other liquids and compressing and forcing fluids, atmospheric air, or other aeriform bodies." Dated Feb. 4, 1859.

Provisional protection was not granted for this invention.

319. S. L. TROTMAN. "Improvements for the more effectually securing or fastening envelopes or other like receptacles, and the more securely affixing postage-stamps or other adhesive labels." Dated Feb. 4, 1859.

This consists, 1, in forming envelopes with a tongue gummed on both sides, and a pocket in the back of the envelope into which the tongue is inserted when the envelope is closed. 2, in protecting the gum from the external action of steam, &c., by coating so much of the paper as may be required to cover the gum with a waterproof material, such as varnish, drying oil, or oil paint. *Patent abandoned.*

320. R. A. BROOMAN. "An improvement in cooling worts and beer." (A communication.) Dated Feb. 4, 1859.

This consists in causing a current of cold water to circulate through passages suitably arranged beneath the vessel containing the worts or beer, and thereby gradually and quickly reducing the temperature of the same. *Patent completed.*

321. R. A. BROOMAN. "Improvements in shirts." (A communication.) Dated Feb. 4, 1859.

This consists in so arranging shirts that buttons on the neck band and front are dispensed with; in giving such an amount of stiffness or support to the front that but little, if any, starch is required; and in making the sleeve without any side opening at the wrist, but simply an aperture for the hand to pass through. *Patent abandoned.*

322. G. H. BAYLIS and F. ROBINSON. "An improved indicator for registering the withdrawal of liquids from vessels." Dated Feb. 4, 1859.

This indicator is composed of a circular box, having a dial on its front surface marked with gills, pints, quarts, &c., up to gallons. On the lower part of this dial a second smaller dial is placed marked with gallons only. A spindle is passed through the centre of the box, having a hand on its outer end, and the other end passes through a barrel over which is wound a cord, one end whereof is secured to the barrel, the other end having a float attached thereto, which enters the top of the cask, and floats upon the surface of the liquid, so that as the liquid falls into the vessel the quantity withdrawn is indicated upon the dial until the vessel becomes empty. The two dials are worked

together within the box by toothed wheels, as in clock-work. *Patent completed.*

323. F. H. MABERLY. "Improvements in obtaining spring power, and in its application to various purposes." Dated Feb. 4, 1859.

The patentee prefers to use box springs with fuses. One or more of each is to be operated upon by levers and ratchets. The ratchet apparatus is affixed by squares to the spindles of the fuses, so as to be moveable at pleasure, and the ratchets are worked by levers operated upon by racks and pinions. The racks are supported or balanced by weights, and these racks worked up and down by double cogged or other pinions, the racks carrying the levers of the ratchets up and down. These double cogged or other pinions are themselves revolved by ratchets and levers, such as aforesaid, operated upon by hand or other power. *Patent completed.*

324. L. BONNEAU. "Improvements in apparatus for registering the time carriages are employed in conveying persons from place to place, and also in moving from place to place when unoccupied." Dated Feb. 4, 1859.

Here two markers, or pencils, and a ring of paper are arranged in connection with the seat of a cab or other vehicle, so that when the vehicle is in motion one of these pencils oscillates and makes a zig-zag mark, and when the seat is depressed by the weight of a passenger the second pencil is caused to mark. *Patent abandoned.*

325. J. M. E. MASSON. "Improvements in apparatus to facilitate working under water." Dated Feb. 4, 1859.

This invention is not described apart from the drawings. *Patent completed.*

326. P. ADIE. "Improvements in apparatus for taking levels and measuring angles." Dated Feb. 4, 1859.

This relates to arranging the instrument known as the ordinary levelling telescope with parts in connection therewith, so that the same may be used as a theodolite. We cannot give space to the details of this invention. *Patent completed.*

327. W. R. J. PACKER. "Improvements in the plough or plough-share, for the purpose of more effectually pulverizing, breaking up, or cutting into small particles the earth or sod separated from the ground by the plough-share." Dated Feb. 4, 1859.

This consists principally of a cylinder placed to the plough-share which moves a wheel, and by means of this wheel a pinion, with or without a square or collet attached, studded with rakes or spikes, revolves, and by such revolution the earth is crushed. *Patent abandoned.*

328. J. HONEYMAN. "Improvements in the construction of ships, vessels, and boats, and in propellers for propelling the same." Dated Feb. 4, 1859.

Here the lower part of the hull of a ship is built of a cylindrical figure, the width of which corresponds to the width of beam at the upper part of the hull. The enlarged portion extends from the bow nearly to the stern, where it is hollowed in so as to form a recess at the parts adjacent to the stern post. The cylindrical portion of the hull projects well out at the stern, where it is enclosed by metal plates or timber, so as to form a flat vertical surface. At this part a screw propeller is fitted, the driving shaft of which is carried through the end disc of the cylindrical part. The propeller consists of a conically-shaped drum, having vanes or blades extending backwards in a curved direction from the apex of the cone to the base. *Patent completed.*

329. A. BARCLAY. "Improvements in electric, magnetic, or electro-magnetic telegraph ropes or conductors, and in machinery or apparatus to be used on board ship for laying or paying out the same." Dated Feb. 4, 1859.

Here the component wires or strands of the cable are covered individually with hemp, &c., and each strand is passed through melted tar, pitch, &c., and afterwards through sand. The strands are passed through squeezing rollers. The whole cable is finally treated in the same way. In paying out cables, after the cable leaves the ship's hold, it passes over a species of elasticated guide block tackle, that is, over a series of upper and lower pulleys, the spindles or centres of which are suspended from the ship by cautehouc, &c. There are modifications included. *Patent abandoned.*

330. W. CLARK. "Improvements in the means or apparatus for preserving grain, flour, eggs, and other vegetable and animal substances." (A communication.) Dated Feb. 4, 1859.

This consists in enclosing the substances to be preserved in a cylinder formed of wooden staves united by iron hoops. This cylinder is enclosed in a tinned iron case, perfectly soldered, to exclude air. This case has at top and bottom a hoop of brass rivetted and

soldered to the cylinder. This brass hoop has a brim or flange, and it is by this flange that the lid is bolted thereto. To render the joint air tight, a thickness of india-rubber is placed between the lid and cylinder. On the metallic casing is rivetted and soldered a plate furnished with a stop cock to place the cylinder in communication with an air pump by which a vacuum is produced. *Patent completed.*

331. F. H. MABERLY. "Improvements in apparatus for corking, for drawing corks, in taps, in the necks of bottles, in the bung-holes of barrels, and in similar articles." Dated Feb. 5, 1859.

The inventor proposes to compress the corks by a screw or screws conjointly with other power, so as to render them fit for putting into the bottle without any other force than that of the finger and thumb. The cork drawer is to be of the needle kind, plain, or screwed, or wormed, easily passing through the cork, and then throwing out spring bars, so that the cork drawer cannot be withdrawn without bringing out the cork. *Patent abandoned.*

332. N. GREENHALGH, W. SHAW, and J. MALLISON, jun. "Certain improvements in the treatment and preparation of yarns or threads previously to dyeing." Dated Feb. 5, 1859.

Here the "cops" of yarn to be treated are placed in a suitable chamber in connection with an apparatus for exhausting the air therefrom; and when the yarn is thus in vacuo, a solution of shumac or catechu is to be introduced and the yarn thoroughly saturated. It is then submitted to the action of "hydro-extractor" to dry out the superfluous moisture, and afterwards placed in vacuo again, and (if to be dyed black) saturated with a solution of iron. It is then dried, and is in a condition to be woven into cloth with a woollen or worsted substance or alpaca, hair, &c. *Patent completed.*

333. E. TINKER. "Improvements in churns." Dated Feb. 5, 1859.

This relates, 1, to rotatory churns, and consists in arrangements whereby the barrel can be set steady or fixed in several different positions as regards its rotation. It relates, 2, to the bungs of churns, and consists in making them of a piece of india-rubber combined with wood. It relates, 3, to an improved air discharge valve, whereby it can be readily taken out and cleaned. The metal portions of the bungs and valves are electro-plated. *Patent completed.*

334. H. ANDERSON. "An improved construction of apparatus for winding window blinds, sun shades, and similar articles on their rollers." Dated Feb. 5, 1859.

This consists of a framing through which is passed two journals, the end of the one being fastened to the blind roller. To this journal is affixed by a stud a steel coiled spring. The other end is fastened to the framing. On the same journal is also a toothed wheel gearing with a small pinion on the other journal; on this latter journal, alongside the pinion, is a ratchet wheel, and on it the end of the lever, to which is attached the cord, is made to rest by a knee-shaped spring. *Patent abandoned.*

335. T. SYKES and B. C. SYKES. "Improvements in obtaining or separating oily, fatty, greasy, tarry, waxy, and resinous substances, from oleaginous seeds, nuts and fruits, wool, silk, hair, cotton, flax, line, hemp, furs, skin, leather, bones, fish, and other animal matters and refuse, woollen and cotton waste and refuse, also textile fabrics and refuse grease produced in various branches of industry, indigo, lac, lac dye, and other dyes." Dated Feb. 5, 1859.

This relates, 1, to the use of bisulphide of carbon as a solvent; and, 2, to the use of hydrostatic pressure, with water or other fluid, to facilitate the percolation of the solution of the oily, waxy, or resinous substances in the bisulphide of carbon or naphtha through the bodies treated, and ultimately to displace it. *Patent completed.*

336. T. R. AYEST. "Improvements in breech-loading guns and other fire-arms." (A communication.) Dated Feb. 5, 1859.

This consists in forming a clear opening through the breech, and applying a closing piece consisting of a cross piece mounted on a joint or hinge pin on one side of the bore. This hinge piece is received in a recess when in position, which with suitable shoulders abuts and holds it close against the back end of the bore. The hinged piece is of considerable thickness, and has a screw bolt or plug piece screwed through it in the direction of the bore, the nose of which enters therein, effectually closing the barrel at the breech, and also fixing the hinged piece securely in its place. The back end of the bore is enlarged, forming a recess into which the nose of the screw enters, the nose or end being somewhat larger than the bore, and which nose abuts against the shoulder so formed. The screw stem projects in the rear of the hinge piece, and has a short hand lever by which

it is turned. When it is turned about a quarter of a revolution, and so as to withdraw the nose of the screw from the bore, the screw meets with a stop in its rotatory motion on its own axis, so that the further movement of the hand lever moves the cross piece on its hinge or joint pin, thus throwing it over out of the line of the barrel, and thereby disclosing the bore, and affording sufficient freedom for loading from behind. The reverse movement of the cross piece and the hand lever effectually closes the breech, and makes the gun ready for firing. *Patent completed.*

337. M. BOOTH and J. FARMER. "Improvements in sizing or stiffening woven fabrics." Dated Feb. 5, 1859.

This consists in so passing the goods through the size that one side thereof only becomes coated, and in so removing the superabundant quantity that it shall not fall again on to them. *Patent abandoned.*

338. G. F. CHANTRELL. "Improvements in the treatment of charcoal after its manufacture or revivification." Dated Feb. 7, 1859.

The patentee proposes to expose the charcoal to the action of the atmosphere by a system of endless travelling bands or aprons arranged horizontally one above another, and stretched upon transverse rollers at each end, through one or both of which motion is communicated to the endless bands. The charcoal is fed to the upper apron of the series from a hopper, having arrangements to regulate the supply of charcoal delivered to the endless bands. *Patent completed.*

339. J. HOLROYD. "An improvement in apparatus used in finishing woollen and other cloths." Dated Feb. 7, 1859.

This applies principally to a machine for turning back the nap, and consists in interposing a sheet of brass or other tinseled between the cloth and the card cylinder, so that only a part of the surface of the cloth is exposed to the action of the cards, thereby producing a pattern on the cloth. *Patent abandoned.*

340. A. LYONS. "A pocket protector." Dated Feb. 7, 1859.

This consists in applying a strip of steel to the mouth of the pocket, so as to be hinged together at one end, and admit of being opened and closed at the other by a hasp, &c. *Patent abandoned.*

341. W. H. CRISPIN. "An improved atmospheric and hydraulic engine for sailing and steam vessels." Dated Feb. 7, 1859.

The elemental power is here obtained by the oscillation of a pendulum, the vibration whereof is caused by the motion of the ship, suitable arrangements of wheel-work being actuated by the pendulum when in oscillation. The power thus obtained may be applied either in a direct manner, or may be used for the condensation or exhaustion of atmospheric air, or for the working of hydraulic arrangements. *Patent abandoned.*

342. M. CURTIS and J. MILLER. "Improvements in certain mules for spinning cotton and other fibrous substances." Dated Feb. 7, 1859.

The patentee claims the application of a shaft and gearing to communicate motion from the tin roller in one carriage to the tin roller in another carriage, where tin rollers are used, and the like means where tin drums are employed to communicate motion from the shaft which drives the drums in the one carriage to the corresponding shaft in the other. *Patent completed.*

343. J. LEE. "Improvements in the manufacture of cranks for steam engines, and other purposes." Dated Feb. 7, 1859.

The bar to be formed into a crank is heated in a furnace, and somewhat upset or thickened at the place where the crank is to be formed. It is then placed in a machine furnished with dies, which are forced towards each other so as to bend the bar to the required form. The upper die is formed with a projection at its centre corresponding to the form of the crank, and has at its two ends friction pulleys to allow the bar to run easily over the surface of the die to furnish the length of bar requisite for the bend. The projection of this upper die when bending a bar to form a crank passes down between two lower dies, which are each furnished with a friction pulley at the upper corner or angle against which the bar is forced by the projection of the upper die, and these friction pulleys are for allowing the bar to run freely over the angles of the dies to supply the length taken down by the projection of the upper die. *Patent completed.*

344. T. SIMS. "Improvements in the application of photography to engraving and printing." Dated Feb. 7, 1859.

The inventor employs a film of collodion, either alone or covered with albumen or gelatine, on a

surface of glass or talc, and he produces the photographic picture upon it either in the wet or dry state in the ordinary manner. He then submits the film to the action of bi-chloride of mercury and ammonio-chloride of gold, to cause the lines of the picture to swell or rise, and become absorbent. He then covers the film with a thin coat of varnish, which speedily dries on the porous raised lines or parts, leaving the other parts wet. He then dusts over the picture a quantity of powdered resin or gum, &c., which adheres to the wet parts. The picture is now in a fit state for transferring to paper, stone, copper, steel, or zinc. *Patent abandoned.*

345. E. T. HUGHES. "Improvements in ovens." (A communication.) Dated Feb. 7, 1859.

This consists in arranging two or more fires under the oven, the heat and smoke of the lower fire passing through the one above by means of the grate bars, which bars may be made of fire-clay or metal tubing; if of the latter they must be filled with water. There are flues with valves suitably arranged for regulating the heat. *Patent abandoned.*

346. J. SMITH. "Improvements in machinery, or apparatus for preparing, and combing wool and other fibrous substances." Dated Feb. 7, 1859.

This consists in the use of a circular currying comb, suitably arranged in connection with other parts; also in the use of a series of rectangular double comb surfaces, arranged and actuated in a manner which we cannot on account of space describe in detail. *Patent completed.*

347. J. WILSON. "Improvements in ventilating mines, and in combining apparatus used for such purpose." Dated Feb. 7, 1859.

This consists in the construction at the mouth of the downcast shaft of the mine of a gasholder or receiver of a capacity and strength proportionate to the quantity and pressure of the atmospheric air required for the supply of the workings of the mine, and for maintaining the purity of its atmosphere. To this receiver is attached a force pump or pumps, and by means of pipes leading to the different parts of the mine, the object of the invention is effected. *Patent abandoned.*

348. T. MOSS. "Improvements in the manufacture of paper and printing ink, suitable for bank notes, bills of exchange, and other documents requiring like security against being copied." Dated Feb. 8, 1859.

In manufacturing paper the patentee combines with the pulp the colouring matter he may desire; and he uses in the preparation of his colours burnt china or other clay, oxide of chromium, or sulphur. In the manufacture of printing inks he employs burnt china or other clay and sulphur, ground up with suitable drying oils or varnishes. *Patent completed.*

349. E. T. HUGHES. "Improvements in machinery or apparatus for sorting and numbering the threads or filaments of silk or other fibrous materials." (A communication.) Dated Feb. 8, 1859.

Here certain defined lengths of the thread or filament are wound on bobbins, and then weighted to determine the numbers. The operation is divided into the process of dividing, cleansing, and doubling, for which a bobbin and a regulating counter may be employed, these two contrivances being subordinate to an arrangement by which the bobbin stops the moment that one or more threads break. *Patent abandoned.*

350. J. HOSKING. "Improvements in the manufacture of lamps." Dated Feb. 8, 1859.

This consists, 1, in causing a greater quantity of air to be brought into direct contact with the wick or burner than heretofore. 2. In bringing two currents of air into contact with the wick, and also in certain arrangements in connection with the chimney. *Patent completed.*

351. G. THOMAS. "A double bottomed horse-shoe." Dated Feb. 8, 1859.

This consists in shoeing horses with two shoes on each foot. One shoe, or the shoe proper, is to be fastened to the hoof by nails. This shoe in the centre part is dovetailed so as to admit of the second shoe being placed thereon. In winter the under shoe may be taken off and replaced by a "roughed" one with the utmost ease and rapidity. *Patent abandoned.*

352. E. BAGNICK. "An improved syringing apparatus for curing leucorrhoea, and similar sexual diseases." Dated Feb. 8, 1859.

This consists of an apparatus whereby the curing of sexual diseases is effected by injection in combination with electricity, which latter acts in connection with the dormant electricity of the human body, so as to produce the desired electrical effect simultaneously with the injection of the fluid. *Patent completed.*

353. W. WALLER. "Improvements in agricul-

tural or farm implements or apparatus." (Partly a communication.) Dated Feb. 8, 1859.

This comprises various improvements in ploughs, harrows, reaping machines, horse or hand rakes, and presses for cheese curds, fruit, &c., the details of which are too voluminous for our pages. *Patent abandoned.*

354. R. R. ROWNTREE. "A portable tea-testing apparatus." Dated Feb. 8, 1859.

This consists in enclosing within an outer case a vessel for containing water for boiling, a gas-burner, and a series of cups and pots fitting one within the other, as also a spoon, together with a length of elastic tubing coiled and contained within a case for communicating from an ordinary gas-burner to the apparatus, and containing the several parts in position when stowed away in the outer case. *Patent abandoned.*

355. J. ASPINALL. "An improvement in the refining of sugar." Dated Feb. 8, 1859.

The patentee claims the method of melting sugar in the refining thereof in such manner that the melting shall take place at or near the surface of the water used to melt the same, and before the sugar comes in contact with the steam, steam-pipes, heated bottom or sides of the pan, or other medium for heating the contents of the pan. Also the employment in pans for carrying on the "surface melting," of two or more perforated false bottoms or plates. *Patent completed.*

356. J. B. REDMAN. "An improvement in the construction of carriage ways." Dated Feb. 8, 1859.

The patentee claims constructing carriage ways with boxes, troughs, and cases of iron adapted and combined, and having surfaces upon which wheels are to travel, with a diamond or other like raised pattern. *Patent completed.*

357. A. CLARK. "Improvements in revolving shutters and blinds, and in apparatus connected therewith." Dated Feb. 8, 1859.

This consists, 1, in making rolling shutters or blinds of sheets of corrugated metal. 2. In making shutters or blinds of fibrous material, combined with strips of steel, or of wire interlaced with the fibrous material. 3. In the application of an endless band of steel to communicate motion to the roller for winding up the shutters and blinds. 4. In the use of strips of tempered steel to connect revolving shutters or blinds to the rollers on which they are coiled. 5. In making revolving shutters and blinds of a series of laths or strips having a semi-circular curve along each edge, the convex of which curved edges are placed in contact to form the exterior of the shutter or blind. 6. In making snail or volute grooves, in continuation of the side grooves, whereby shutters and blinds may be coiled and uncoiled simply by pushing them up into, or pulling them down out of, such volute grooves. *Patent completed.*

358. W. CLARK. "Improved protectors for tobacco plants." (A communication.) Dated Feb. 8, 1859.

The inventor encloses the stalk in a small tube or pipe of baked clay. *Patent abandoned.*

359. T. S. CRESSY. "Improvements in machinery used in the manufacture of casks." Dated Feb. 8, 1859.

This consists in a peculiar combination of apparatus applied to a lathe to facilitate the cutting of the heads of casks, such apparatus being put in motion by the rotation of the wood which is to form the head of a cask. *Patent completed.*

360. J. JUCKES. "Improvements in stoves or fire-places." Dated Feb. 8, 1859.

Here an inclined bottom is fitted to each stove, under which inclined bottom is a drawer containing the fresh fuel, and the pushing in of this drawer causes the fresh fuel to rise up into the fire. *Patent abandoned.*

361. E. WILKINS. "Improvements in flower vases." Dated Feb. 9, 1859.

The arrangements here adopted are not described apart from the drawings. *Patent completed.*

362. J. S. JOSEPH. "Improvements in coke ovens, and in cooling and extinguishing coke." Dated Feb. 9, 1859.

The patentee constructs an oven with an arched roof having an aperture or apertures. Over this roof he places another roof, from which flues are carried down the sides and under the bottom of the oven, and away to a chimney, and a regulated quantity of air is admitted into the oven and flues to effect the combustion of the gases. The coke when finished is pushed out by a plate and a rack and pinion. The floor of the oven is constructed with a shallow recess into which water is introduced, and the steam arising from this water cools the coke and carries off the sulphur. *Patent completed.*

363. W. ARCHER. "Certain improvements in Jacquard machines." Dated Feb. 9, 1859.

This consists, 1, in effecting the ascent of one "griff" and the descent of another simultaneously by a toothed pinion situated between the two griffs, and taking into a rack upon each griff, the pinion being caused to partake of the required reciprocating semi-circular motion by the ordinary means, so as to lift one griff and lower the other by the same semi-circular movement of the pinion. 2. In so connecting a helical or other spring with the "batten," that upon any wrong working of the machine the said spring shall yield to the extra pressure and prevent breakage of the machine. 3. In mounting the blades in the griffs upon pivots or centres at each end, upon which they may vibrate, so as to allow them to yield to the wire hooks. *Patent abandoned.*

364. H. JEFFERIES. "An improvement in castors." Dated Feb. 9, 1859.

Within a socket or collar of metal, a cup of glass, earthenware, or steel is fitted in an inverted position; into this cup a sphere of wood is placed, and is secured in its position by a ring screwed or otherwise fixed over it, but so as to allow of the sphere turning freely within its cup. When the castor is in use the sphere rests on the surface, supporting the piece of furniture of which the castor forms part, and when the piece of furniture is moved the sphere turns and allows it to run freely. *Patent abandoned.*

365. J. CROSSLEY. "Improvements in the means employed when cleaning printed yarns." Dated Feb. 9, 1859.

According to a patent granted to the inventor August 21, 1856, zinc or metal plates placed between the supports to the yarns are employed for catching the droppings of the colours of one set of yarns from falling into and mixing with colours of the yarns below. Now, the first part of the present invention is to obviate the condensation of steam underneath the plates. For this purpose these plates are so formed as to admit of the introduction into the inside thereof of steam or other heating media, which serves to keep the plates constantly hot, and so prevent condensed steam gathering underneath the plates, and thereby dropping the yarns below. The invention consists, secondly, when steaming printed yarn, in the use of troughs placed underneath the cradles, such troughs containing water heated to a great degree, and the steam arising from the hot water passes at once through the yarn placed on trays immediately above it, thus fixing the colours of the yarn, and the steam then passes away out at the top of the chamber, and carries away with it the impure gases arising from the colouring matter. The outer framework of the cradle frames is made of cast-iron. *Patent completed.*

366. J. TAYLOR and C. WILD. "Improvements in self-acting mules for spinning and doubling." Dated Feb. 9, 1859.

Here the spindles, carriages, and fallers, and the drawing rollers, are of ordinary arrangement. The spindles are driven from a "rim pulley" in the first motion shaft; the carriage is drawn out and taken in by bands, drums, and scroll drums, similar to those used in ordinary mules. On the completion of each stretch, the belt is traversed from the fast to the loose driving pulley; the taking-out motion is put out of gear, and the backing-off motion is put into gear by the direct action of the carriage on suitable levers. We cannot give space to the details of the invention. *Patent abandoned.*

367. J. H. JOHNSON. "Improvements in fire-arms." (A communication.) Dated Feb. 9, 1859.

This relates to self-primers for fire-arms, and appertains more particularly to that class of self-primers where the magazine is contained in the hammer of the lock of the fire-arm. It consists in so arranging the parts that the person using the arm can always see at a glance whether his magazine contains primers or not, without the trouble of taking the whole to pieces for that purpose. *Patent completed.*

368. G. BOWER. "Improvements in apparatus for the manufacture of illuminating gas." Dated Feb. 9, 1859.

The specification of this invention is too elaborate for us to quote it at sufficient length for an intelligible abstract. *Patent completed.*

369. J. E. MCCONNELL. "Improvements in steam boilers, and in the generation and treatment of steam." Dated Feb. 9, 1859.

This consists, 1, in so arranging and fitting up the tubes of steam boilers that the heated current of gaseous matter passing through them may be effectually commingled and applied to the tube surface. 2. In a mode of superheating steam. *Patent completed.*

370. W. E. NEWTON. "An improved mode of bleaching and purifying or refining sugar and vege-

table juices or extracts." (A communication.) Dated Feb. 9, 1859.

This consists in the use of some highly oxidised substances, such as the peroxides of manganese and iron, either artificial or natural, or the carbonates of these bases. *Patent completed.*

371. E. HERRING. "Improvements in the mashing and fermenting of grain for the production of alcohol." Dated Feb. 9, 1859.

This consists in adding to the mashes of unmalted or malted grain a carbonated or a caustic alkali (to be neutralised or not at pleasure), firstly, for the solution of the gluten, and, secondly, for the entire preservation of the works from the formation of acetic acid, and for the neutralisation of the existing lactic acid, which latter may be liberated at pleasure by the addition of an acid (muriatic being preferable), forming the neutral muriate of soda or common salt in small quantity, restoring the lactic acid in its original quantity, and generating carbonic acid, and consequently virgin fermentation. *Patent completed.*

372. W. E. NEWTON. "Certain improvements in breech-loading fire-arms, and in cartridges to be used in such fire-arms." (A communication.) Dated Feb. 9, 1859.

This relates to the construction of the breech and chamber of fire-arms, and to the mode of opening the chamber to receive a cartridge, by which, with the use of a cartridge case made of some impermeable and elastic substance, such case is made to serve as a packing to make the breech-joint perfectly tight when the explosion of the charge takes place. It also relates to the means of locking the barrel and breech together to keep the breech-point close, and to the means of unlocking these parts. *Patent completed.*

373. H. P. BURR. "Improvements in railway carriages and waggons." Dated Feb. 10, 1859.

This consists in applying to the axles or wheels of railway carriages a wheel and pinion, or a wheel and screw, or a chain wheel and pinion, or a friction wheel and pinion, or other contrivance for multiplying power. There are handles or hand-wheels or ratchet handles to the same, by turning or moving which a carriage may be stopped or started with facility. *Patent completed.*

374. J. YOUNG. "An improvement or improvements in the construction of knobs and the roses used for connecting knobs with doors, and with the cases of locks and latches, and other like fastenings." Dated Feb. 10, 1859.

This invention is not described apart from the drawings. *Patent completed.*

375. J. G. TAYLOR. "Improvements in writing materials, and the manufacture thereof." Dated Feb. 10, 1859.

This comprises various improvements in inkstands, pencils, pens, penholders, and brushes for cleaning pens, the details of which are too voluminous to be quoted here. *Patent abandoned.*

376. W. A. COVERT. "An improved self-acting railway switch." (A communication.) Dated Feb. 10, 1859.

Here the engine and tender and the last carriage of each train are provided with two small rollers capable of being raised up or lowered by the driver or guard, and so connected together that the depressing of the roller on one side shall cause the raising of that on the other side. If the engineer desires the train to run off on to a siding at the right hand of the main line, or otherwise to diverge to the right before reaching the points, he depresses the right hand roller. As the engine approaches the points, this roller coming against the inclined plane, will thrust the moveable rail on that side outwards, and by means of the cross bar draw the switches into the required position. The projection on the cross-bar gears into a peculiar form of locking cam, consisting of a circular plate provided with a notch and two projecting fingers or catches, and capable of turning on a pin on the tie connecting the switches, which prevents the switches from being moved by any other agency than the action of the moveable rails. By the use of this switch the necessity for employing pointmen is entirely dispensed with. *Patent completed.*

377. R. J. ELLIS. "Improvements in apparatus for lifting sunken vessels and other submerged bodies." Dated Feb. 10, 1859.

This consists of one or more cylindrical or other shaped vessels of large capacity. Each vessel has two or more floating ball valves which open inwardly, and a large spring valve or valves which open outwardly when the internal pressure is greater than the external pressure. These pontoons are fitted internally with a number of hydraulic cylinders placed in a longitudinal line with the floating and spring valves. These hydraulic cylinders are connected together by pipes which form passages for water from the bottom

of the interior of one cylinder to another, and are fitted with pistons and piston-rods, which work through stuffing-boxes in the bottom of the vessel. The lifting chains are attached to the outer ends of the piston-rods by which arrangement the strain will be equal on each. One or more of these pontoons are placed side by side, and attached together by strong beams, on which a deck can be laid, and a mast or masts rigged for sailing them from place to place. When these pontoons are to be brought into operation, by allowing the floating valves in the bottom to work, the water will enter the vessel, and cause it to sink to the wreck; &c., the lifting chains being made fast to the object required to be lifted, are then attached to the ends of the hydraulic piston-rods. The water is then forced from the interior of the pontoon through the openings of the floating valves by atmospheric air forced therein through a pipe from the surface by an air pump, which is worked on board an attendant vessel. *Patent completed.*

378. G. L. STROCKS. "Improvements in steering apparatuses." Dated Feb. 10, 1859.

This invention is not described apart from the drawings. *Patent completed.*

379. H. INGER. "The improvement of blinkers used by horses whilst drawing, to be called the 'Patent Safety Blinker.'" (A communication.) Dated Feb. 10, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

380. B. BURROWS. "Improvements in looms for weaving narrow fabrics." Dated Feb. 10, 1859.

This consists, 1, in so arranging the various parts of the loom employed that the same loom may be used to produce, opposite each rod or slay, or opening in the batten, either a fabric having the wefts of two shuttles, one on one side and the other on the other side, or two fabrics of lesser width, each having the weft of only one shuttle introduced therein. 2. In arranging such descriptions of looms in sections or parts, all capable of being worked together as an ordinary loom. *Patent completed.*

381. C. L. PERRY. "An agricultural implement for paring and ploughing land." Dated Feb. 10, 1859.

This consists of a framing supporting two, three, or more instruments of the kind commonly employed for paring or skim ploughing land, the said instruments being so arranged as to be capable of being raised and lowered at will. *Patent abandoned.*

382. M. BILLING and W. KLOHN. "A method of, and apparatus for, decolourising tea." Dated Feb. 11, 1859.

This consists in exposing the tea to the action of steam. *Patent abandoned.*

383. J. EVANS. "An improvement in 'Hansom' cabs." Dated Feb. 11, 1859.

Instead of connecting the scroll ends on the front part of the floor of the cab to the shafts by rigid iron stays, the patentee connects them thereto by springs of steel or other suitable metal, the tail end of the said springs being attached to scroll loops or other connections fixed upon the under side of the shafts. The back stay connecting the floor of the cab to the heel of the shaft, instead of being rigid, is furnished with a butt hinge joint at or near its centre, having only a very slight amount of movement, but still sufficient to allow of the play necessary for the full development of the invention. *Patent completed.*

384. J. PARKINSON. "A certain improvement in coffins." Dated Feb. 11, 1859.

This consists in manufacturing coffins of glass. *Patent abandoned.*

385. N. BENNETT. "Improvements in the construction of brooms or brushes for sweeping or cleansing streets, roads, and thoroughfares, also applicable to domestic purposes." Dated Feb. 11, 1859.

The inventor lengthens the heads and forms them of one half the width, so as not to increase their weight, but as the handle (if placed in the centre) would be found awkward in the hands of the operator, he proposes forming it Y shaped, either in pieces, or by splitting the handle about one third of its length, inserting each of the prongs in the broom-head about one-third distance from each end thereof. As in decreasing the width of the broom-head now in use the power of resistance would be lessened, he proposes, so as to obtain sufficient resistance, that the bone, &c., whereof the brush is composed shall be of different strengths and sizes, and that the lesser size should be placed in that part of the broom-head farthest from the operator. *Patent abandoned.*

386. H. BENCE. "Improvements in apparatus for the manufacture of paper." Dated Feb. 11, 1859.

This relates to a mode of manufacturing paper so that the web as it leaves the paper-making or air-drying machine is coated with a mixture, in which way papers of every shade of colour may be made,

and the web may be coated upon one or both sides. It is then dried, and subjected to the glazing process which produces an enamelled paper. *Patent completed.*

387. G. HYDE. "A pen for producing a copy or copies of a letter or other writing simultaneously with the production of the original." Dated Feb. 11, 1859.

The inventor employs a pen of extreme hardness or rigidity, so that when writing upon paper with ordinary ink, having beneath the paper carbonic or similar transferring medium, and under that medium paper intended for the copy, an exact copy of the writing will be produced. *Patent abandoned.*

388. R. COGAN. "Improved instruments for crushing and mixing solid and liquid substances." Dated Feb. 11, 1859.

This invention is not described apart from the drawings. *Patent completed.*

389. H. A. BARTLETT. "Improvements in machinery to be used with or without the plough for clearing and cleaning land from weeds." Dated Feb. 11, 1859.

This invention consists, as applied to a plough, of a framework extending lengthwise beyond the ground iron, and vertically to the shafts or handles. This framework has attached to it a driving wheel, which gives motion to a shaft or drum from which pegs or teeth project, and in their revolution take up the weeds. These teeth come in contact with another drum or roller provided with rakes, pegs, or teeth, for freeing the first of weeds. *Patent abandoned.*

390. C. JACKSON. "Improvements in the action of pianofortes." Dated Feb. 11, 1859.

In order to obtain the escapement of the fly or hopper the patentee fixes to the front of it at right angles, or nearly so, a straight projecting piece, the end of which comes underneath a stop carried by a stem fixed in the block on which the fly or hopper is mounted. This stop is adjustable by a screw, and by it the fly or hopper can be arranged to escape at the proper time from the hammer or other instrument on which it acts. Below the projection from the fly or hopper he sometimes places another adjustable stop, also mounted on the block carrying the hopper. This second stop is employed in substitution of the rail ordinarily used to prevent the fly or hoppers from falling farther from the hammers or instruments on which they act than is necessary. *Patent completed.*

391. J. GRIMES. "Improvements in beer-engines." Dated Feb. 11, 1859.

This consists in applying to beer-engines cooling cylinders, such cylinders being surrounded with ice, and through which cylinders the beer, &c., is caused to pass after it leaves the pump cylinder, and before it passes to the cock or spout by which it is drawn off. *Patent completed.*

392. H. RANSFORD. "An improvement in building ships and other vessels." Dated Feb. 11, 1859.

This consists in constructing each ship or vessel wider at the floor than at the water line, the fore and aft parts below the water-line being modified accordingly. *Patent abandoned.*

393. G. HADWEN and J. WADSWORTH. "Improvements in Jacquard apparatus applicable to power-looms." Dated Feb. 12, 1859.

This consists in employing two card cylinders, and two sets of hooks and needles, two needle boards, and two spring boxes, both sets of hooks and needles being united to one harness by double neck-bands. The patentees cause each cylinder to work half the number of cards of the pattern. *Patent completed.*

394. H. LEA. "Improvements in changing or reversing motion." Dated Feb. 12, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

395. T. WILLIS and G. CHRELL. "Improvements in machinery for spinning, twisting, doubling, and winding yarns and threads." Dated Feb. 12, 1859.

This relates to a previous patent, and consists in employing revolving friction discs for imparting motion to the bobbins or spindles, which discs serve as pressers for building the yarn or thread on to the bobbins or spindles, or the discs may be used for driving the bobbins or spindles, while the building of the yarn or thread on the bobbins or spindles is effected by pressers of the usual construction; also in varying the speed of the bobbins or spindles and yarn guides according to the increasing diameter of the yarn or thread wound on the bobbins. *Patent completed.*

396. C. B. MOATE. "Improvements in the manufacture of nuts, screw-bolts, spikes, and other headed fastenings." (A communication.) Dated Feb. 12, 1859.

This consists, under one head, in causing the shanks of headed fastenings to be burred or upset so as to cause a swell on the part on which the head is to be

cast, and then a foundryman's flask is prepared, in which a pattern is moulded, and in so much of the space which represents the shank the prepared shank before described is placed, and into the hollow in the sand or loam left for the head the melted iron is run in, which, uniting with the burred shank, completes the bolt, &c. *Patent abandoned.*

397. J. CRABTREE. "Improvements in the manufacture of bobbins and spools." Dated Feb. 12, 1859.

The object here is to form bobbins and spools of paper or cardboard, by which economy of cost and room, with considerable reduction of weight, are obtained. The inventor describes special apparatus for the purpose. *Patent abandoned.*

398. S. H. HUNTLY. "Improvements in cooking apparatus." Dated Feb. 12, 1859.

This consists of a combined cooking apparatus, by which the process of roasting, baking, steaming, and boiling may be carried on simultaneously. *Patent completed.*

399. T. WHITE and G. JENKINS. "Improvements in apparatus for raising and lowering ships along inclined slips." Dated Feb. 12, 1859.

This relates to a peculiar construction and arrangement of hydrostatic apparatus, whereby a continuous heaving action is obtained in raising or lowering ships from or into the water along an inclined slip. *Patent completed.*

400. J. and J. BENNETT. "An improvement in refrigerators for cooling beer and worts." Dated Feb. 12, 1859.

The object here is to obtain an extensive cooling surface in a refrigerator of a limited size. It consists in fitting two or more tiers of pipes in the refrigerator, and in connecting four or more of these pipes with the cold-water main, so arranged that the whole may be cleaned without difficulty. *Patent completed.*

401. G. G. W. and J. BETJEMANN. "Improvements in book slides." Dated Feb. 12, 1859.

This consists in fitting vulcanized caoutchouc or other springs to the underpart of the bottom of slides, in such manner that the slide supports shall always return to the position from whence they have been drawn upon the extra book or books being taken from the slide. To ensure the action of the springs the patentees fix rollers at or near the outer end of the under part of the travelling slabs or of the flaps. These rollers prevent the slabs being pressed down out of the level with the bottom of the grooves in which the slabs travel, by the weight of the books which may be placed upon them. *Patent completed.*

402. W. G. RAWBONE. "Improvements in fire-arms and ordnance." Dated Feb. 12, 1859.

This consists in the formation of an elongated breech chamber, for the reception of the powder, of less diameter than that of the bore of the barrel, and in forming an annular shoulder in the front of this chamber for the projectile to rest upon, and thereby prevent the powder being compressed by the projectile being rammed down thereon. *Patent abandoned.*

403. G. T. BOUSFIELD. "Improvements in revivifying the scarlet colour of woollen cloth, lace, and embroidery, in use for military and other garments and furniture." (A communication.) Dated Feb. 12, 1859.

To restore the wool to its original scarlet colour it is necessary only to apply the following composition:—citric acid, 300 grains; carbonate of potash, 150 grains; water, 7,500 grains. The citric acid is dissolved separately in 4,500 grains of water, and the carbonate of potash in 3,000 grains of water, after having first pounded each of these substances separately in a mortar to facilitate the solution. When the solution of each of these substances is complete the whole is mixed together; there is then obtained 7,500 grains of liquid composition suitable for restoring the colour of scarlet wool. *Patent abandoned.*

404. H. GARDNER. "Improvements in machinery for breaking and preparing flax and other fibres." Dated Feb. 12, 1859.

The patentee employs four breaking or crimping rollers arranged together in a frame. One of the rollers is placed in the centre, and the other three are ranged around and kept up to it by springs. The flax, straw, &c., is fed to the machine between the centre and the top roller; it afterwards passes between the centre roller and the two other rollers, and is brought back to and delivered on the same side of the machine as it was fed into it. The fibre as it passes from these rollers is caused to pass through a series of small grooved or plain rollers arranged in pairs, the upper and lower roller of each pair being pressed towards each other by springs. These rollers are mounted in two separate frames, each frame carrying every alternate pair. One of the frames has an up and down motion communicated to it by a crank and connecting rod, or otherwise, and the rollers are thus caused so to rub the fibre as to make

the woody parts of the straw already broken by the larger rollers to fall out. *Patent completed.*

406. R. BELL. "Improvements in separating and recovering wool from fabrics composed of wool, or wool in connection with cotton and other vegetable substances." Dated Feb. 12, 1859.

The patentee takes muriate of manganese, such as is ordinarily obtained as a residuum in the manufacture of bleaching powder, in which state it is mixed more or less with chloride of iron. The rags, composed of rags and vegetable fibre, such as cotton or flax, are steeped in a solution of the above muriate of manganese, which rots or decomposes the vegetable and leaves uninjured the animal fibre therein. The two are then separated by processes well known. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Aug. 5, 1859.

1806. M. A. F. Mennons. A system of columns or monuments to be employed as sentry boxes, branch post and other offices, telegraph and fire-engine stations. (A communication.)

Dated Aug. 13, 1859.

1809. R. D. Clegg and T. Saunders. Improvements in locks.

Dated Aug. 23, 1859.

1926. W. H. Hill. An improvement in the manufacture of boxes or cases, and in fastenings for the same.

1928. W. Hollins and F. Hyde. Improvements in power looms for weaving, part of which improvements is also applicable to other machines driven by power.

1930. T. Richardson. Improvements in treating copper ores.

Dated Aug. 24, 1859.

1931. G. Pearson. Improved machinery for manufacturing boots and shoes.

1933. J. Henry and J. E. H. Andrew. Improvements in looms for weaving.

1934. J. Blake. Improvements in steam and vacuum gauges.

1935. D. Russell and J. Russell. Improving the means of docking and lifting ships out of the water for the purpose of examining and cleaning their bottoms, effecting any necessary repairs, fixing new screw propeller, rudder, raising sunken vessels, or any thing else for which it is desirable to get at any portion of a vessel generally under water.

1936. T. Briggs. Improvements in the manufacture of tarpauling.

1937. J. Murray. Improvements in the preparation and bottling or preserving of carbonated cod liver oil and other aerated liquids.

1938. C. T. Judkins. Improvements in sewing machines.

Dated Aug. 25, 1859.

1939. H. Smith and T. W. Ashby. An improved construction of harrow. (A communication.)

1940. L. Perkins. Improvements in mills. (A communication.)

1941. A. P. Chamberlain. Improvements in machinery or apparatus for cutting cork, part of which improvements is also applicable to cutting paper, caoutchouc, and other substances.

Dated Aug. 26, 1859.

1943. J. Furrell. A lock protector, consisting of an adhesive shield or cover to be placed over the key-hole of a lock for the purpose of ensuring that any access to the interior of the lock shall be readily detected.

1945. T. Bird. Improvements in castors.

1946. J. M. Hetherington. Improvements in machinery or apparatus for carding cotton, wool, and other fibrous materials.

1947. H. Grundt. Improvements in life-boats.

1948. W. MacLellan. Improvements in rolling or shaping iron for railway spikes and other purposes.

1949. C. T. Boutet. A new mechanical mill proper for milling every sort of grains, dried or torrefied, such as coffee and cocoa.

Dated Aug. 27, 1859.

1950. C. Hanson. An improvement in the chronometer escapement of a watch.

1951. F. Wrigley. Certain improvements in the construction of the permanent way of railways.

1952. J. R. Rostron. Improvements in furnace bars.

1953. W. H. Balmain. Improvements in the manufacture of glass, and other vitrified substances.

1954. T. Craven. Improvements in ball cocks or valves.

1955. G. Bell. Improvements in reaping and mowing machines.

1956. J. Heckethorn. Improvements in candles

and wicks, also in lamps or candlesticks for using with the same.

1068. F. Rettig. Improvements in the form and construction of anchors. (Partly a communication.)

Dated Aug. 29, 1859.

1060. T. Meriton. Improvements in governors for regulating the speed of marine and other engines and machinery.

1061. C. Kerman. An apparatus to prevent the sinking of vessels through leakage, for lifting and floating vessels off when stranded, and for raising and floating sunken vessels.

1062. J. R. Howarth. Certain improvements in machinery or apparatus for calendering and finishing textile fabrics or other surfaces.

1063. W. Clark. Certain improvements in sewing and stitching by machinery. (A communication.)

1065. D. Todd. Improvements in machinery or apparatus for carding and treating or preparing fibrous materials.

1066. B. Baugh. Certain improved machinery or mechanical arrangements for raising or giving form to articles formed of sheet metal, such as knobs, thimbles, ferrules, and parts of umbrella and parasol furniture, button shells, and other such like small articles.

1067. G. S. Fleming. A head-rest, suitable for keeping the head in a comfortable position in travelling, sitting, or lying down.

Dated Aug. 30, 1859.

1060. J. B. Barnes and J. Loach. Certain improvements in oars for impelling boats, as also in the rowlocks in which they work.

1071. J. Hare. Improvements in pianofortes.

1075. C. and J. Chambers. Improvements in apparatus for sawing staves and other forms of wood.

1077. R. F. and E. Drury. Improvements in vices.

Dated Aug. 31, 1859.

1070. J. Nuttall. Certain improvements in and applicable to, machinery used in preparing and spinning cotton and other fibrous materials.

1081. R. Beverley. Improvements in wet gas meters.

1083. S. Middleton. Improvements in the mode or method of uniting and otherwise manufacturing articles of leather, and such like materials, and in the apparatus and machinery connected therewith.

1085. A. Smith. Improvements in machinery for the preparation of cocoa nut fibre.

1091. J. Chatterton. Improvements in the manufacture of tubes of gutta percha, and other substances capable of being moulded in a similar manner when in a plastic state, and also in coating wire and other cores with such substances.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2032. J. J. Sieber. Improvements in power looms. (A communication.) *Dated Sept. 6, 1859.*

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Sept. 13, 1859.)

1093. A. Jumelais. Obtaining power.
1094. J. Ferguson and J. McGaveny. Fasteners.
1097. J. Basford. Expressing clay through dies.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

CONTRACTORS' RAILS, &c., Scotland.—About 42 lbs. per yard; also earth-waggons, and 2 ft. 6 in. wrought-iron wheels and axles. Apply, Mr. W. Thompson, contractor, Hawick.

RAILWAY STORES, Ireland.—For the Waterford and Limerick Railway, in such quantities as they may require in the year commencing Oct. 1. To include iron (bar and plate); boiler tubes for engines (iron), and feed-pipes; nails, steel, files, and tools; chairs and sleepers; keys, trenails, and screw augurs; timber, &c. Particulars and forms, Sept. 20 inclusive, Waterford Terminus.

COPPER, Navy.—For the Chatham Dockyard: in ingots of 112 lbs. each, 60 tons; in ingots of 140 lbs. each, 65 tons; tough cake, 45 tons; copper cakes about 14 lbs. each, without lead, 30 tons. Conditions and forms, Somerset-place, London. Tenders, 2 o'clock Sept. 20.

SEWERAGE, Leamington.—4,250 lineal yards of brick sewers, for the outfall drainage of the district, the construction of works for the defecation or deodorisation of the sewerage therefrom, the alteration, diversion, & improvement of the river Leam, between the Adelaide-bridge, at Leamington, and the river Avon at Armscote, in the borough of Warwick: the construction of a weir across the said river, and other works connected with the above. Plans, and bills of quantities, and further

particulars, on application to Mr. Morgan, surveyor to the Local Board of Health, Town-hall, Leamington. Specification and form of tender on application to the clerk's office, Town-hall, on payment of 10s. Tenders to Sept. 26.

RESERVOIR EMBANKMENT, &c., Halliwell, near Bolton.—Plans, sections, and specifications, office of Mr. H. Eaton, Mount Slon, Radcliffe, near Manchester. Tenders to the 28th inst.

LIGHTHOUSE LANTERN, Trinity House.—For the Dungeness Lighthouse. Forms, specifications, &c., of the Corporation of Trinity House, London, up to 24th inst. Tenders, Sept. 27.

COAST-GUARD STATION, Ireland.—At Cloutarf, in the County of Dublin. Plans, &c., Board of Public Works, Dublin. Each proposal to be for a lump sum, and to be accompanied by a detail giving quantities and prices.

CURRACH TOWER, Ireland.—To the Roman Catholic church at Dunmore, County Galway. Plans, elevations, &c., by Mr. J. S. Butler, architect, 16 Hume-street, Dublin. Plans at the residence of the parish priest, Dunmore; or of the architect; where tenders, Sept. 23.

PRISON, Galway.—For adapting present county prison to the separate system of confinement. Plans, &c., Mr. S. U. Roberts, county surveyor. Tenders to the Chairman of the Board of Superintendence per the governor of the gaol, Sept. 24.

CURRACH WORK, Ireland.—For repairing and painting externally the churches of St. George (Belfast), Kilcorkfield (Ballymena); St. Matthew, Lisburn (Brookmudge); all County Antrim. Loughgilly and Middleton, County Armagh. Ballycawley, County Tyrone. For repairing the churches of Drumschoose (Newtownlismavady) County Derry. Fahau Lower (Buncrana), County Donegal. And Rose, County Mayo. All according to specifications, with the resident ministers of the parishes. Tenders to Ecclesiastical Commissioners for Ireland, 24 Upper Merion-street, Dublin, Sept. 23.

CHURCH RESTORATION, Hemel Hempstead.—Plans, Mr. White, vicar's churchwarden, and office of Mr. Christian, 10 Whitehall-place. Tenders to Sept. 26th.

WORKHOUSE, East Grinstead.—For the erection of a new union workhouse, at East Grinstead, Sussex. Drawings, specifications, quantities, Messrs. Peck and Stevens, High-street, Maidstone. Tenders to Mr. W. Head, clerk to guardians, East Grinstead, Sept. 22.

CHURCH, Southampton.—Drawings and specifications at office of the architects, Messrs. Hayley and Son, Cross-street, Manchester. Tenders to Sept. 20th.

SCHOOLS, Neath Abbey.—Plans for alteration of the British schools, at office of the Neath Abbey Iron Company, or of Mr. Richardson, C.E., Queen-street, Neath. Tenders to Sept. 21st.

SCHOOLROOM, &c., Christchurch, Hants.—Plans and information at the Royal Engineer's office, Gosport. Tenders to Sept. 19th.

TOWN-HALL, Newcastle-under-Lyme.—Plans for remodeling, copies of quantities, and other information at office of Messrs. Ward and Son, architects, Hanley. Tenders to Sept. 21th.

MANAGER OF COPPER AND IRON WORKS.—The office of resident manager of the coal, iron, copper, smelting, and tin-plate works, at Crom Avon, in South Wales, belonging to the Governor and Company of Copper Mines in England, will become vacant in a few months. A deputy manager is also required. Similar previous occupation necessary. Application to the Court of Assistants, 10 New Broad-street Mews, London, Charles Frewer, Secretary.

TRAVELLER.—For engineering tools. Address, stating age and salary, with references, to B. 79 Post-office, Leeds.

REMARKS.—We are unable to report any improvement of business in Metals. Our Markets continue very quiet.

LAWRIE AND HAGGER, Metal Brokers

33 Lombard-street, E.C.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 23, 1859.

THE GREAT EASTERN EXPLOSION.

INTO what a weltering flood of pros and cons, questionings and cross-questionings, swearings and counter-swearings, have we to plunge in entering once more upon this subject! It is only because we know that above the weltering flood the simple truth is securely floating, and because we hope to bring that safely to land, that we make the plunge, and strike out towards our object.

For the outside reader who has nothing to guide him but such reports as the newspapers have been enabled to publish, and who has no time to peruse even them with studied care, the simplest and most natural thing to do is to fix the blame impetuously upon either Mr. Scott Russell on the one side, or upon the Company (in which are included nearly all the remaining witnesses at the inquest) upon the other, and then cast the whole question out of his mind, and have done with it. But as there are persons who wish to look deeper into the matter than the newspapers can possibly admit them, and who have the time and patience to dig even to the bottom of it for the truth, and who, moreover, are too much alive to the justice that is due from man to man either to put the blame of one man upon a dozen, or to heap the blame of a dozen upon one—as there are such persons, we say, it becomes incumbent upon us to set about unravelling the mystery, and displaying the truth, of this very sad affair. To do this we must in the first place advert to a few facts antecedent to the late trip to Portland.

Every one will remember that early in the month of August last two notable celebrations took place on board the Great Eastern at Deptford. In those celebrations the Chairman and Directors of the Great Ship Company joined, making speeches themselves, accepting eulogies from Lord Stanley and others, and subsequently receiving a written acknowledgment of their enterprise from numerous members of the House of Commons. Now, what was the avowed occasion of those celebrations? This—and let the reader mark it carefully—the completion of Mr. Scott Russell's contract for finishing the ship (in so far as she was then to be finished) in a certain number of weeks! Mr. Campbell and Mr. Jackson, M.P.—the Chairman and the Deputy-Chairman—distinctly and lavishly eulogised Mr. Scott Russell for the admirable zeal and skill which he had shown in performing what he had undertaken.

Again: towards the end of August, a general meeting of the shareholders of the Great Ship Company was held, and during it Mr. Jackson, M.P., made a speech which was very generally published. From that speech we extract the following passage. After explaining how it was that the contract came to be given to Mr. Scott Russell, Mr. Jackson proceeded:—"And now, instead of the work occupying six months, as Mr. Brunel anticipated, it has been completed in four months; during which time as much work has been done as required in building a 120-gun ship. I say, if any man retrieved a position, and came out gloriously, it is Mr. Scott Russell. The work that he has done is incredible. Such an example of what can be effected by mind and muscle is unsurpassed." Mark the first sentence: "it has been completed in four months"—that is Mr. Jackson's statement in August.

Again: several days before the Great Eastern

left the Thames we met Mr. Scott Russell in Great George-street, Westminster. The ship was, of course, spoken of, as was the approaching trial trip also; and one of the remarks of Mr. Russell was, "the Company have invited me, and have authorised me to invite a limited number of my friends." The fact was stated as a simple and natural one, and of course accorded fully with the knowledge we had of the contract's previous completion.

Further: the day before the ship left her moorings at Deptford, we went on board and met Mr. Russell there. To our suggestion that we feared he must be exceedingly busy, he replied that, on the contrary, he had little or nothing to do, those of his men who were on board being lent to the Company, and not employed on any business of his.

Before we separated from Mr. Russell on the last-named occasion, a gentleman belonging to Messrs. Boulton and Watt's firm (the makers of the screw-engines) joined us, and to him Mr. Russell made some observations to which late events have given great importance in our minds, as they bear directly upon the much-vexed question of Mr. Russell's position during the late trip. They were to the following effect, although we cannot, of course, report them verbatim: "As I shall be on board," said he, "and we must all do what we can, I think the best thing I can do will be to go upon the paddle-bridge, and prevent any wrong or mis-taken instructions being given to my engines. I think you had better do the same. We can then see that the engines are not pushed too much for the first day or two. You know, to-morrow is not a trial trip at all. The business of to-morrow is to get the ship round to Portland, and nothing else. But if we don't keep our own eyes upon our engines something may go wrong, and for the sake of all parties we must avoid that. Perhaps it may be a convenience to Captain Harrison if I take the engine-room telegraph and myself send every message down for him; no one will complain of our assistance." This, we say with perfect certainty, was the tenor of Mr. Russell's observations; and in reply, the gentleman spoken to said he thought highly of Mr. Russell's proposal, and suggested that as the telegraph to the screw-engine room was within a few feet of the other, Mr. Russell might do his firm good service by working both of them. The whole conversation of course implied that Mr. Russell believed he had no duties and no responsibilities resting upon him in the way of business; but that he felt anxious to assist the owners and officers of the ship, and that he could do this best by guarding the engines which he had built for them from being subjected to any accidents from above. When it is remembered that there was to be a captain and two pilots on board—that the navigation down the river was certain to be most intricate, occasioning many turnings ahead and astern—that the ship was of an immense length, so that the pilot in the bows might think it necessary to send instructions aft on his own responsibility—that for the first time both screw and paddle-engines were to be worked together in the same ship—and that a hundred or two of passengers might all be crowding round the officers of the ship and round the engine-room at once—it will be seen that Mr. Russell's determination was a most wise and important one. It will also, we think, be observed that it involved no sort of responsibility beyond that of seeing that when the engines were to be turned ahead they were not turned astern—that when they were to be put on to half-speed they were not put on to full-speed—and so forth. By no ingenuity, however subtle, can it be said to have saddled

him with the charge of the officers and men down in the boiler-rooms.

Now, from the moment the voyage was commenced at Deptford down to the time of the explosion, Mr. Russell managed both telegraphs, as he had proposed to do, and managed them with greater assiduity and care than any other man could have been expected to evince. That in doing this he sometimes refused to press the engines quite as much as some of the many official persons on board desired, is in no way inconsistent with the simple and voluntary service which he was rendering; nor does the fact in any way prove that he had "charge" of the engines in any other than a very limited sense of that term. It was, as we said in our letter written from the ship at Purfleet, the mere "working" of the engines that was temporarily under his control, and by no means the engines themselves, much less the boilers.

Having thus stated what we personally know, beyond all controversy, in the matter, we turn to the evidence given at the inquest. And in doing this we must take with us two hypotheses: 1, That Mr. Scott Russell was supposed to have completed his contract, and was on board the ship as the guest of the Directors, lending useful assistance, but in no sense exercising authority over the Company's staff of engineers or over the apparatus under their care; 2, That his contract was not completed, that the engines were not the Company's but his own, and that he had full authority over both men and apparatus. One of these hypotheses must stand; the other must fall to the ground: which is to stand, and which fall?

Before answering this question we must observe that both Mr. Russell and the Company appear to have been guilty of much business laxity or the question at issue could never have been raised. There should have been fewer verbal, and more written, understandings between them. Had the Company been less satisfied with Mr. Russell, or had he been less trustful of them, this would undoubtedly have been the case. As it was, they each trusted the other, implicitly but most unwisely, and the consequences of their mutual reliance are before us. Still, it should be understood that it was confidence, and not mistrust, which led to the present perplexities. But those perplexities are not the less on that account. The absence of everything but tacit understandings has left all the principals concerned in the ship free to swear just as they pleased, or as their feelings, rather than their knowledge, dictated. Hence we have the Chairman of the Company, the Deputy-Chairman, the Captain of the ship and the Chief Engineer of the ship, all of course swearing on one side; and on the other side Mr. Russell swearing for himself. Had the interests been reversed, who knows with how little difficulty some, at least, might have taken views opposed to their present evidence, without in any way violating their consciences?

In our judgment, therefore, the evidence tendered at the inquest carries but exceedingly little weight with it, and will scarcely help us at all to arrive at a choice of one or other of the hypotheses which we have before us. It seems to be admitted by all parties, however, that the whole staff of engineers who were in attendance upon the boilers and engines were in the Company's pay, and had signed the ship's articles. They were therefore under Mr. McLennan's orders. Mr. McLennan, it is true, washes his hands clean of all charge of them by saying that he committed the care and the responsibility of them to Mr. Dixon—Mr. Russell's manager! But he does not say that he had specific authority, or indeed any authority, for doing this,

and only justifies the proceeding by saying that Mr. Brunel and Mr. Campbell had given him general instructions to let the contractors alone. So that we really must consider them under his charge, and regret that he should ever for a moment have considered otherwise.

As to Mr. Dixon, he unquestionably was a good deal in the paddle engine-room; but then he was equally in the dining-saloon among Mr. Russell's friends, and dined at the same table as ourselves only an hour or two before the accident. No one, perhaps, saw more of the active assistance which he rendered at times than we; but we all the time understood perfectly well that he was doing what he did voluntarily, and from a desire to aid the officers of the ship, as his employer was aiding them, to the best of his ability.

Which hypothesis, then, are we to adopt? We state frankly, and without reserve, that we can accept the first only. Where evidence "in black and white" cannot be produced, facts may be strangely transformed to serve useful purposes. But even if this question should be taken into a court of law, and it should be there decided that Mr. Russell's business on board the ship was not completed when she left the Thames, we should still believe that its completion had been tacitly acknowledged by the Company. Indeed, have we not already recited the acts and words of the heads of the Company to that effect?

With the facts which we have laid before them in their possession, our readers will know what value to attach to the letters of Mr. J. H. Dillon and some others who have written to the *Times*, saying that they saw Mr. Scott Russell giving orders on board the ship. They may have believed they were exposing some terrible discrepancies; but all they saw was perfectly consistent with the view we have taken of the matter—or rather, not the view which we have taken, but that which has been forced upon us by our own senses.

The preceding portion of this article was written on Wednesday evening. This day, Thursday, we find in the *Times* the following letter sent up by Mr. Scott Russell from Weymouth. How entirely it coincides with all that we have stated will be seen at a glance:—

Sir,—I observe in the *Times* of to-day letters from "A Passenger-Shareholder" and from "Spectator," pretending to contradict my evidence and Mr. Dixon's regarding the part I took, and the part I did not take, in the management of the paddle-wheel engines; and I find another from a Mr. Dillon, of a previous date.

I frankly admit that I communicated probably 100 messages, in the course of the voyage, from the bridge to the paddle-engine room.

I as readily admit that my chief assistant was in the paddle-engine room, giving all the assistance in his power to carry the orders I transmitted into effect.

I equally admit that my son Norman assisted me in transmitting some of those messages, and that he counted for me the strokes of the engines, and reported to me every five minutes their condition and speed.

It is perfectly true that at one time the screw-engines went faster than the paddle-wheel engines, and at another time the paddle-wheel engines faster than the screw.

But all your correspondents have omitted to state (what they could equally have stated if they were competent witnesses and wished to be just), that I transmitted the same number of orders in the same manner to the screw-engines, which were not made by me, and where no engineer of mine was assisting.

The fact is I merely worked the telegraph, and transmitted the necessary instructions to both engines from the pilot and captain, in such a manner as would best give effect to their wishes, and cause the vessel to perform the evolutions they desired.

But is it just or fair to argue from such circumstances that I was in responsible charge of the working of both sets of engines? I am sure Mr. Blake will not say I was responsible for his engines because I concerted telegraph arrangements with him.

I may further state that I did not go into either engine-room, and I could not even see the paddle-engines work from where I stood. My engines, and, as I imagine, those of Messrs. Watt and Co., were in the hands of the company's engineers serving under the ship's articles. Out of 170 persons, servants of the Company, employed on the engines and boilers, only four were appointed by the Company on my recommendation, and an equal number on Messrs. Watt and Co's recommendation.

Had the paddle-engines remained my property; had they been worked on my responsibility; had the trial trip been in any degree mine, I should have taken upon myself the entire and absolute control of the whole paddle-wheel and boiler department, and should not have permitted any one to touch either engines or boilers who had not been absolutely appointed by me, and been solely responsible to me. As it was, the Company refused my offer to recommend to them competent persons for the entire staff of the paddle-wheel engines and boilers, and only accepted my recommendation for the appointment of their first four engineers.

The management of the engines and boilers being thus placed in the hands of the Company's own servants, all I could do was to render the utmost assistance in my power, as every maker of engines naturally would do, when he had the opportunity, in a work of extraordinary magnitude.

I remain, Sir, your obedient servant,

J. SCOTT RUSSELL.

Weymouth, Sept. 20.

We shall not pursue this subject further. We should perhaps have satisfied some few readers better if we had said less, and had let the chivalrous Directors and officers of the Company heap the blame of this unhappy affair upon the man whom they lately combined to extol. But it is not for us to see a distinguished engineer and shipbuilder made a scapegoat of commercial mismanagement. The professions made by Mr. Scott Russell, both privately and publicly, have been perfectly consistent from the time of the great celebrations in August down to the very moment of the explosion. The professions made by the Company's Directors are not so; much of what they have declared at Weymouth in September being in flat opposition to what they said at Deptford and London in August. As it is our duty to make known the rights of the matter, we can do no other than support the man who has both truth and consistency on his side.

As to the purely scientific aspect of the case, there is little to be gleaned either from the inquiry at Weymouth or from the explosion itself. If, as seems to be the case, the "tap" was shut, we need no theories of steam-decomposition to account for the explosion and its effects. If the tap was open, as Mr. Russell in his evidence said it may possibly have been, then the sudden admission of cold water upon the over-heated plates of the water-vessel, and the consequent flashing-up of more steam than the stand-pipe could carry off, was in all probability the occasion of the accident. Neither hypothesis offers anything new to science. Terrible explosions are frequently occurring from both causes, and no amount of parade which we might make—by engraving sketches of the funnel and casing, or by other means—would serve scientific men one bit.

The practical result of the whole disaster should be,—better management on board the Great Eastern. Turn the sworn evidence how we may, we cannot escape the conviction that the management of the ship was a sad bungle. There were far too many masters on board, and too great a disposition to make other people masters. Because Mr. Russell went up to the paddle-bridge telegraphs, half-a-dozen of the responsible officers of the ship straightway declare him master of 170 of the Company's servants! Because Dixon lends a helping hand at the engines, the chief engineer of the ship declares him master of all the men around him! This sort of thing will not do. Let Captain Harrison at

once become supreme on board, and after appointing every other man to his work, inflexibly insist upon his doing it.

SIR HOWARD DOUGLAS'S IMPROVEMENT OF THE SCREW PROPELLER.

We have had so little leisure lately that we have been unable to do an act of justice which seems in fairness to be demanded of us—that of defending the gallant and veteran Sir Howard Douglas from the attack which Mr. Robert Griffiths made upon him on the 2nd inst. in the columns of the leading journal.

On the 27th of August an elaborate article appeared in the *Times* in commendation of Sir Howard's improvements in the screw propeller, the greater portion of which article was quoted in our columns. Three days afterwards Mr. Griffiths replied in the letter of which we complain. Had his remarks been confined to the fact that in the *Times*' retrospect of the progress of screw propulsion no mention had been made of his improvements we should, of course, have nothing to say against them; nor should we, indeed, had he further stated that in his propellers the blades were of a form somewhat resembling that recommended by Sir Howard. But when Mr. Griffiths has the boldness to claim under his patent of 1849 precisely what Sir Howard has proposed, and further menaces Sir Howard with litigation if he ventures to proceed with his plans, it becomes necessary for us to inform the public that Mr. Griffiths is going beyond his legitimate bounds.

Mr. Griffiths' propeller, and his patents also, are of course familiar to us; but in order that we might speak with perfect confidence upon the subject we have taken the pains to refer to the specifications of his patents, and we now say in all confidence that these patents give him no right whatever to interfere with Sir Howard's modification of the Admiralty screw. If he thinks they do, he is mistaken, and his threat of legal proceedings amounts to nothing. But even if Mr. Griffiths were justified in a legal sense in thus threatening the gallant General, one would have thought that the distinct avowal of the *Times*—to the effect that Sir Howard would steadfastly refuse all pecuniary interest in the matter—would have saved so valuable and aged an officer from Mr. Griffiths' menace. But it requires a finer sense of honour than Mr. Griffiths seems to possess to understand even such an avowal as that properly; to him it was only a proof that Sir Howard is "liberal of other people's property"—a charge which a sensible man would have been very slow indeed to bring against Sir Howard Douglas!

Mr. Griffiths concludes his letter by suggesting to Sir Howard that he should "familiarise himself with what has been done by others," and "avoid being misled by interested patent agents and injudicious friends." This is certainly not very polite or modest language, coming from a man like Mr. Griffiths to a man like Sir Howard Douglas! We should like to know how many readers of the *Times* read it with approbation. But its want of candour, which few readers only will detect, is even worse than its want of good taste, which every one must observe; for Sir Howard might have read Mr. Griffiths' specification over and over all the rest of his days and never have found occasion to alter or extend his own published views upon the screw in the slightest degree. As to the suggestion about interested patent agents—if that be intended to refer to us as the earliest advocates of Sir Howard's improvements, it can be answered at once by saying that Sir Howard is not, nor ever was, a client of ours. We never

performed a single business transaction with him in reference either to this or any other subject. We hope this plain assurance will fully satisfy the delicate mind of Mr. Griffiths.

A CHINESE LESSON ON NATIONAL DEFENCE.

We cannot afford to lose 464 men in the mud of a Chinese river without some kind of recompense, and perhaps the very best kind possible is that of drawing a lesson on river defence from the late disaster. We think we see a very important one that may be drawn from it, viz., that we may with confidence trust for the defence of English rivers to local gun-rafts in conjunction with booms, chains, stakes, or other like obstructions.

What have we seen on the Peiho? This: that a fleet of gun-boats, however gallantly handled, may speedily be crushed by the fire of batteries—if they can only be stopped for a time within range. Had the river been clear of obstructions, the little squadron would doubtless have run the gauntlet of the forts without serious injury, in the same manner as our light vessels passed within range of many a Russian fort in the Sea of Azoff during the late war, without losing a man. This even the Chinese knew, and therefore brought our gunboats to rest under their guns by the stakes of which we have heard so much, and then cut them up at will. But—it has been said—the attack was badly planned; the cart was put before the horse; the forts should have been taken in reverse by a land force before the steamers were brought within range. That is doubtless correct enough. But suppose the forts had been gun-rafts, stationed adrift above the stakes, inaccessible to a land force, and so as to concentrate their fire upon the stakes: by what mode of procedure could these have been silenced? By none whatever save that adopted by Admiral Hope, which ended so disastrously.

Here, then, is instruction, and hope too, for us who are so often alarming ourselves about squadrons of French gunboats ascending the Thames and levying contributions upon London. A few heaps of stakes piled upon the banks, with a few dozens of casks, fathoms of rope, and other simple stores by the side of them, together with a supply of guns and gunners, and our riverside towns may in a day be made as safe as art can make them!

As this suggestion may be carried out so very simply and cheaply no notice will, we presume, be taken of it. Yet it is not without the sanction of professional men of eminence. The foremost of those who advocate it is Captain Cowper Phipps Coles, R.N., who "knocked the Lady Nancy raft together in a night," and with her "went in and burnt Taganrog," and thus inspired Punch's famous song, beginning—"O jaw till you're frantic of vessels gigantic, With hundreds of guns, and with thousands of crew, Jack's want's of the oddest, a vessel so modest As just does the work as he wants her to do—He doesn't condemn none, your big Agamemnon, Your Dukes and your Alberts, as long as a street; They're mighty imposing, but when he's for closing, A taut Lady Nancy is worth the whole fleet."

This able officer has, as we have stated in a previous article, published a pamphlet on the subject. This can be had at Messrs. Clowes and Sons, Charing-cross, and we recommend our readers to get it. A few words from men of experience in such matters is worth volumes of mere speculations; and we hope Captain Coles will speak out even yet more fully upon this important question, especially as he has already promised "a future pamphlet." If we are determined to spend millions on doubtful defences, it will still be well to know how reliable ones may be secured for next to nothing.

FOREMEN ENGINEERS.

MANY of the master-engineers, master-ship-builders, and other masters in this country are undoubtedly among the ablest men of the age. Some of them have risen from the ranks of working-men; others have prepared themselves for their positions by prolonged study and observation; and many of both classes are doubtless unsurpassed in their professions. But, however able a master may be, if his business be large and flourishing we shall be sure to find, if we inquire, that its greatness and prosperity do not all spring from him. Beneath those great men whose names distinguish so many firms, there is another class who, to the world, are for the most part nameless, but to whom we really owe much of our manufacturing wealth and eminence. We allude to that strong-handed, clear-headed, noble class of men whom we call "foremen." These are they to whom the nation is mainly indebted for its ascendancy in almost all the useful arts. The Brunels and the Russells, the Lockes and the Stephensons, the Maudslays and the Penns, the Nasmyths and the Napiers, the Whitworths and the Fairbairns, the Lancasters and the Armstrongs, the Barrys and the Scotts—these are the men whose names are perpetually flashed in our faces as we look upon the great works that surround us; and it is with no grudging spirit that we behold their pre-eminence. At the same time it is but just that we should sometimes remember those less distinguished but equally honourable men from whose brains first springs many an idea which afterwards brings fame to their masters, and without whose skill we never could have won the position we now hold among the nations.

Our thoughts were turned afresh to this subject a few days since by a meeting of the Association of Foremen Engineers which we attended. It was a real interest in the Society that took us there, and it was with an increase of that interest that we retired from the gathering. We now advert to the event, not simply in response to the request which the excellent President of the Association—Mr. Joseph Newton (of the Royal Mint, we believe)—made to the scientific press, but because of the claims which foremen engineers have upon the regards of the public.

It would appear from what transpired on the occasion referred to (as will be seen from the report published on another page) that the officers of this Association have reason for believing that the employers view their proceedings with a certain amount of distrust. Their chief ground for their belief seems to be found in the fact that open and personal countenance of the Association is seldom manifested by the employers. We hope this has arisen from nothing worse than a misapprehension on their part. And in order to remove any such misapprehension, so far as is in our power, we would refer our readers in a sentence or two to the history of the Society. From the Secretary's report it appears that it was established seven years since, primarily as a foreman's benefit society. No questions of trade politics, or political economy have ever been discussed by its members, whose meetings, at the outset, were but mere friendly re-unions. More recently, however, they have met with a further object—the very laudable one of imparting to each other the benefit of their respective professional experiences, in the shape of scientific papers, read at monthly meetings. Surely there is nothing in all this but what employers should delight in and encourage!

For the future, then, we hope to hear no more of anything like distrust of this Association on the part of employers. On the contrary, we

anticipate learning that employers are evincing both wisdom and good feeling by enrolling themselves as honorary members of the Association, and giving occasional attendance to its meetings. It is in every way most desirable that our really practical and experienced men—which these foremen, almost to a man, are—should be encouraged to communicate their knowledge to each other and to the world. It is a firm persuasion of ours that if all which foremen sometimes know were known also by masters, we should hear of fewer failures than we do. Masters often live in a region of ideas; but their foremen are for ever handling facts: and we know perfectly well that the former, unchecked by the latter, lead many a clever man astray. By all means, then, let us not only countenance the work of this Association, but further it in every way possible to us. Already nearly seventy members have undertaken to carry it on, and there are doubtless scores of patriotic foremen throughout the country who will be proud to share their labours and their honours. We hope soon to hear that they are doing so, and hope also that during the next year we may have an opportunity of enriching our columns with many valuable contributions from their pens.

THE PRINCE CONSORT ON SCIENCE:

BEING THE OPENING ADDRESS OF HIS ROYAL HIGHNESS THE PRINCE CONSORT TO THE BRITISH ASSOCIATION.

GENTLEMEN OF THE BRITISH ASSOCIATION,—Your kind invitation to me to undertake the office of your President for the ensuing year could not but startle me on its first announcement. The high position which science occupies, the vast number of distinguished men who labour in her sacred cause, and whose achievements, while spreading innumerable benefits, justly attract the admiration of mankind, contrasted strongly in my mind with the consciousness of my own insignificance in this respect. I, a simple admirer and would-be student of science, to take the place of the chief and spokesman of the scientific men of the day, assembled in furtherance of their important objects!—the thing appeared to me impossible. Yet, on reflection, I came to the conclusion that, if not as a contributor to or director of your labours, I might still be useful to you, useful to science by accepting your offer. Remembering that this Association is a popular Association, not a secret confraternity of men jealously guarding the mysteries of their profession, but inviting the uninitiated, the public at large to join them, having as one of its objects to break down those imaginary and hurtful barriers which exist between men of science and so-called men of practice—I felt that I could, from the peculiar position in which Providence has placed me in this country, appear as the representative of that large public which profits by and admires your exertions, but is unable actively to join in them; that my election was an act of humility on your part, which to reject would have looked like false humility, that is, like pride, on mine. But I reflected further, and saw in my acceptance the means, of which necessarily so few are offered to Her Majesty, of testifying to you, through the instrumentality of her husband, that your labours are not unappreciated by your Sovereign, and that she wishes her people to know this as well as yourselves. Guided by these reflections, my choice was speedily made, for the path of duty lay straight before me.

If these, however, are the motives which have induced me to accept your flattering offer of the Presidency, a request on my part is hardly necessary that you will receive my efforts to fulfil its duties with kind indulgence.

If it were possible for anything to make me still more aware how much I stand in need of this indulgence, it is the recollection of the person whom I have to succeed as your President

—a man of whom this country is justly proud, and whose name stands among the foremost of the naturalists in Europe for his patience in investigation, conscientiousness in observation, boldness of imagination, and acuteness in reasoning. You have no doubt listened with pleasure to his parting address, and I beg to thank him for the flattering manner in which he has alluded to me in it.

The Association meets for the first time to-day in these regions and in this ancient and interesting city. The poet, in his works of fiction, has to choose and anxiously to weigh where to lay his scene, knowing that, like the painter, he is thus laying in the background of his picture, which will give tone and colour to the whole. The stern and dry reality of life is governed by the same laws, and we are here living, feeling, and thinking under the influence of the local impressions of this northern seaport. The choice appears to me a good one. The travelling philosophers have had to come far, but in approaching the Highlands of Scotland they meet nature in its wild and primitive form, and nature is the object of their studies. The geologist will not find many novelties in yonder mountains, because he will stand there on the bare backbone of the globe, but the primary rocks, which stand out in their nakedness, exhibit the grandeur and beauty of their peculiar form, and in the splendid quarries of this neighbourhood are seen to peculiar advantage the closeness and hardness of their mass, and their inexhaustible supply for the use of man, made available by the application of new mechanical powers. On this primitive soil the botanist and zoologist will be attracted only by a limited range of plants and animals, but they are the very species which the extension of agriculture and increase of population are gradually driving out of many parts of the country. On those blue hills the red deer, in vast herds, holds undisturbed dominion over the wide heathery forest, until the sportsman, fatigued and unstrung by the busy life of the bustling town, invades the moor to regain health and vigour by measuring his strength with that of the antlered monarch of the hill. But, notwithstanding all his efforts to overcome an antagonist possessed of such superiority of power, swiftness, caution, and keenness of all the senses, the sportsman would find himself baffled had not science supplied him with the telescope and those terrible weapons which seem daily to progress in the precision with which they carry the deadly bullet, mocking distance, to the mark.

In return for the help which science has afforded him, the sportsman can supply the naturalist with many facts which he alone has opportunity of observing, and which may assist the solution of some interesting problems suggested by the life of the deer. Man also, the highest object of our study, is found in vigorous, healthy development, presenting a happy mixture of the Celt, Goth, Saxon, and Dane, acquiring his strength on the hills and the sea. The Aberdeen whaler braves the icy regions of the Polar Sea, to seek and to battle with the great monster of the deep: he has materially assisted in opening those icebound regions to the researches of science; he fearlessly aided in the search after Sir John Franklin and his gallant companions, whom their country sent forth on this mission, but to whom Providence, alas! has denied the reward of their labours, the return to their homes, to the affectionate embrace of their families and friends, and the acknowledgements of a grateful nation. The City of Aberdeen itself is rich in interest for the philosopher. Its two lately united Universities make it a seat of learning and science. The collection of antiquities, formed for the present occasion, enables him to dive into olden times, and, by contact with the remains of the handiworks of the ancient inhabitants of Scotland, to enter into the spirit of that peculiar and interesting people, which has always attracted the attention and touched the hearts of men accessible to the influence of heroic poetry. The Spalding Club, founded in this city for the preservation of the historical and literary remains

of the north-eastern counties of Scotland, is honourably known by its important publications.

Gentlemen, this is the 29th anniversary of the foundation of this Association; and well may we look back with satisfaction to its operation and achievements throughout the time of its existence. When, on the 27th September, 1831, the meeting of the Yorkshire Philosophical Society took place at York, in the theatre of the Yorkshire Museum, under the presidency of the late Earl Fitzwilliam, then Viscount Milton, and the Rev. W. Vernon Harcourt eloquently set forth the plan for the formation of a British Association for the promotion of science, which he showed to have become a want for his country, the most ardent supporter of this resolution could not have anticipated that it would start into life full-grown, as it were, enter at once upon its career of usefulness, and pursue it without deviation from the original design, triumphing over the oppositions which it had to encounter in common with everything that is new and claims to be useful. Gentlemen, this proved that the want was a real and not an imaginary one, and that the mode in which it was intended to supply that want was based upon a just appreciation of unalterable truths. Mr. Vernon Harcourt summed up the desiderata in graphic words, which have almost identically been retained as the exposition of the objects of the Society, printed at the head of the annually-appearing volume of its transactions:—"To give a stronger impulse and more systematic direction to scientific inquiry—to promote the intercourse of those who cultivate science in different parts of the empire, with one another and with foreign philosophers—and to obtain a more general attention to the objects of science, and a removal of any disadvantages of a public kind which impede its progress."

To define the nature of science, to give an exact and complete definition of what that science, to whose service the Association is devoted, is and means, has, as it naturally must, at all times occupied the metaphysician. He has answered the question in various ways, more or less satisfactorily to himself or others. To me, science, in its most general and comprehensive acceptance, means the knowledge of what I know, the consciousness of human knowledge. Hence, to know is the object of all science; and all special knowledge, if brought to our consciousness in its separate distinctiveness from, and yet in its recognised relation to the totality of our knowledge, is scientific knowledge. We require, then, for science—that is to say, for the acquisition of scientific knowledge—those two activities of our mind which are necessary for the acquisition of any knowledge—analysis and synthesis; the first, to dissect and reduce into its component parts the object to be investigated, and to render an accurate account to ourselves of the nature and qualities of these parts by observation; the second to recompose the observed and understood parts into a unity in our consciousness, exactly answering to the object of our investigation. The labours of the man of science are therefore at once the most humble and the loftiest which man can undertake. He only does what every little child does from its first awakening into life, and must do every moment of its existence; and yet he aims at the gradual approximation to divine truth itself. If, then, there exists no difference between the work of the man of science and that of the merest child, what constitutes the distinction? Merely the conscious self-determination. The child observes what accident brings before it, and unconsciously forms its notion of it; the so-called practical man observes what his special work forces upon him, and he forms his notions upon it with reference to this particular work. The man of science observes what he intends to observe, and knows why he intends it. The value which the peculiar object has in his eyes is not determined by accident, nor by an external cause, such as the mere connexion with work to be performed, but by the place which he knows this object to hold in the general universe of knowledge, by the relation

which it bears to other parts of that general knowledge.

To arrange and classify that universe of knowledge becomes therefore the first, and perhaps the most important, object and duty of science. It is only when brought into a system, by separating the incongruous and combining those elements in which we have been enabled to discover the internal connexion which the Almighty has implanted in them, that we can hope to grapple with the boundlessness of his creation, and with the laws which govern both mind and matter.

The operation of science, then, has been systematically to divide human knowledge, and raise, as it were, the separate groups of subjects for scientific consideration into different and distinct sciences. The tendency to create new sciences is peculiarly apparent in our present age, and is perhaps inseparable from so rapid a progress as we have seen in our days; for the acquaintance with and mastering of distinct branches of knowledge enables the eye, from the newly-gained points of sight, to see the new ramifications into which they divide themselves in strict consecutiveness and with logical necessity. But in thus gaining new centres of light, from which to direct our researches, and new and powerful means of adding to its ever-increasing treasures, science approaches no nearer to the limits of its range, although travelling further and further from its original point of departure. For God's world is infinite; and the boundlessness of the universe, whose confines appear ever to retreat before our finite minds, strikes us no less with awe when, prying into the starry crowd of heaven, we find new worlds revealed to us by every increase in the power of the telescope, than when the microscope discloses to us in a drop of water, or an atom of dust, new worlds of life and animation, or the remains of such as have passed away.

Whilst the tendency to push systematic investigation in every direction enables the individual mind of man to bring all the power of which he is capable to bear on the specialities of his study, and enables a greater number of labourers to take part in the universal work, it may be feared that that consciousness of its unity which must pervade the whole of science if it is not to lose its last and highest point of sight, may suffer. It has occasionally been given to rare intellects and the highest genius to follow the various sciences in their divergent roads, and yet to preserve that point of sight from which alone their totality can be contemplated and directed. Yet how rare is the appearance of such gifted intellects! and if they be found at intervals, they remain still single individuals, with all the imperfections of human nature.

The only mode of supplying with any certainty this want, is to be sought in the combination of men of science representing all the specialities, and working together for the common object of preserving that unity and presiding over that general direction. This has been to some extent done in many countries by the establishment of academies embracing the whole range of the sciences, whether physical or metaphysical, historical or political. In the absence of such an institution in this country, all lovers of science must rejoice at the existence and activity of this Association, which embraces in its sphere of action, if not the whole range of the sciences, yet a very large and important section of them, those known as the *inductive sciences*, excluding all that are not approached by the inductive method of investigation. It has, for instance (and, considering its peculiar organization and mode of action, perhaps not unwisely), eliminated from its consideration and discussions those which come under the description of moral and political sciences. This has not been done from undervaluing their importance and denying their sacred right to the special attention of mankind, but from a desire to deal with those subjects only which can be reduced to positive proof, and do not rest on opinion or faith. The subjects of the moral and political sciences involve not only opinions but feelings; and their

discussion frequently rouses passions. For feelings are "subjective," as the German metaphysician says—it—they are inseparable from the individual being—an attack upon them is felt as one upon the person itself; whilst facts are "objective" and belong to everybody—they remain the same facts at all times and under all circumstances: they can be proved; they have to be proved, and when proved, are finally settled. It is with facts only that the Association deals. There may for a time exist differences of opinion on these also, but the process of removing them and resolving them into agreement is a different one from that in the moral and political sciences. These are generally approached by the deductive process: but if the reasoning be ever so acute and logically correct, and the point of departure, which may be arbitrarily selected, is disputed, no agreement is possible; whilst we proceed here by the *inductive* process, taking nothing on trust, nothing for granted, but reasoning upwards from the meanest fact established, and making every step sure before going one beyond it, like the engineer in his approaches to a fortress. We thus gain ultimately a roadway, a ladder by which even a child may, almost without knowing it, ascend to the summit of truth, and obtain that immensely wide and extensive view which is spread below the feet of the astonished beholder. This road has been shown us by the great Bacon; and who can contemplate the prospects which it opens, without almost falling into a trance similar to that in which he allowed his imagination to wander over future ages of discovery!

From amongst the political sciences it has been attempted in modern times to detach one which admits of being severed from individual political opinions, and of being reduced to abstract laws derived from well-authenticated facts. I mean political economy, based on general statistics. A new association has recently been formed, imitating our perambulating habits, and striving to comprehend in its investigations and discussions even a still more extended range of subjects, in what is called "Social Science." These efforts deserve our warmest approbation and good will. May they succeed in obtaining a purely and strictly scientific character! Our own Association has, since its meeting at Dublin, recognised the growing claims of political economy to scientific brotherhood, and admitted it into its statistical section. It could not have done so under abler guidance and happier auspices than the Presidency of the Archbishop of Dublin, Dr. Whately, whose efforts in this direction are so universally appreciated. But even in this section, and whilst statistics alone were treated in it, the Association as far back as 1833 made it a rule that, in order to ensure positive results, only those classes of facts should be admitted which were capable of being expressed by numbers, and which promised, when sufficiently multiplied, to indicate general laws.

If, then, the main object of science—and I beg to be understood, henceforth, as speaking only of that section which the Association has under its special care, viz., inductive science—if, I say, the object of science is the discovery of the laws which govern natural phenomena, the primary condition for its success is: accurate observation and collection of facts in such comprehensiveness and completeness as to furnish the philosopher with the necessary material from which to draw safe conclusions.

Science is not of yesterday. We stand on the shoulders of past ages, and the amount of observations made, and facts ascertained, has been transmitted to us and carefully preserved in the various storehouses of science; other crops have been reaped, but still lie scattered on the field; many a rich harvest is ripe for cutting, but waits for the reaper. Economy of labour is the essence of good husbandry; and no less so in the field of science. Our Association has felt the importance of this truth, and may well claim, as one of its principal merits, the constant endeavour to secure that economy.

One of the latest undertakings of the Association has been, in conjunction with the Royal Society, to attempt the compilation of a classified catalogue of scientific memoirs, which, by combining under one head the titles of all memoirs written on a certain subject, will, when completed, enable the student who wishes to gain information on that subject to do so with the greatest ease. It gives him, as it were, the plan of the house, and the key to the different apartments in which the treasures relating to his subject are stored, saving him at once a painful and laborious search, and affording him at the same time an assurance that what is here offered contains the whole of the treasures yet acquired.

While this has been one of its latest attempts, the Association has from its very beginning kept in view that its main sphere of usefulness lay in that concentrated attention to all scientific operations which a general gives to the movements of his army, watching and regulating the progress of his impetuous soldiers in the different directions to which their ardour may have led them, carefully noting the gaps which may arise from their independent and eccentric action, and attentively observing what impediments may have stopped, or may threaten to stop, the progress of certain columns.

Thus it attempts to fix and record the position and progress of the different labours, by its reports on the state of sciences published annually in its transactions; thus it directs the attention of the labourers to those gaps which require to be filled up, if the progress is to be a safe and steady one; thus it comes forward with a helping hand in striving to remove those impediments which the unaided efforts of the individual labourer have been or may be unable to overcome.

Let us follow the activity of the Association in these three different directions.

The reports on the state of science originate in the conviction of the necessity for fixing at given intervals, with accuracy and completeness, the position at which it has arrived. For this object the General Committee of the Association entrusts to distinguished individuals in the different branches of science the charge of becoming, as it were, the biographers of the period. There are special points in different sciences in which it sometimes appears desirable to the different sections to have special reports elaborated; in such cases the General Committee, in its capacity of the representative assembly of all the sciences, reserves to itself the right of judging what may be of sufficient importance to be thus recorded.

The special subjects which the Association points out for investigation, in order to supply the gaps which it may have observed, are—either such as the philosopher alone can successfully investigate, because they require the close attention of a practised observer, and a thorough knowledge of the particular subject; or they are such as require the greatest possible number of facts to be obtained. Here science often stands in need of the assistance of the general public, and gratefully accepts any contributions offered, provided the facts be accurately observed. In either case the Association points out *what* is to be observed and *how* it is to be observed.

The first is the result of the same careful sifting process which the Association employs in directing the issue of special reports. The investigations are entrusted to specially-appointed committees or selected individuals. They are in most cases not unattended with considerable expense, and the Association, not content with merely suggesting and directing, furnishes by special grants the pecuniary means for defraying the outlay caused by the nature and extent of the inquiry. If we consider that the income of the Association is solely derived from the contributions of its members, the fact that no less a sum than £17,000 has, since its commencement, been thus granted for scientific purposes, is certainly most gratifying.

The question *how* to observe resolves itself into two—that of the scientific method which is to be

employed in approaching a problem or in making an observation, and that of the philosophical instruments used in the observation or experiment. The Association brings to bear the combined knowledge and experience of the scientific men, not only of this but of other countries, on the discovery of that method which, while it economises time and labour, promises the most accurate results. The method to which, after careful examination, the palm has been awarded, is then placed at the free disposal and use of all scientific investigators. The Association also issues, where practicable, printed forms, merely requiring the different heads to be filled up, which, by their uniformity, become an important means for assisting the subsequent reduction of the observations for the abstraction of the laws which they may indicate.

At the same time most searching tests and inquiries are constantly carried on in the Observatory at Kew, given to the Association by Her Majesty, the object of which is practically to test the relative value of different methods and instruments, and to guide the constantly progressive improvements in the construction of the latter.

The establishment at Kew has undertaken the further important service of verifying and correcting to a fixed standard the instruments of any maker, to enable observations made with them to be reduced to the same numerical expression. I need hardly remind the inhabitants of Aberdeen that the Association, in one of the first years of its existence, undertook the comparative measurement of the Aberdeen standard scale with that of Greenwich—a research ably carried out by the late Mr. Bailly.

The impediments to the general progress of science, the removal of which I have indicated as one of the tasks which the Association has set for itself, are of various kinds. If they were only such as direction, advice, and encouragement would enable the individual, or even combined efforts of philosophers, to overcome, the exertions of the Association which I have just alluded to might be sufficient for the purpose. But they are often such as can only be successfully dealt with by the powerful arm of the State or the long purse of the nation. These impediments may be caused either by the social condition of the country itself, by restrictions arising out of peculiar laws, by the political separation of different countries, or by the magnitude of the undertakings being out of all proportion to the means and power of single individuals, of the Association, or even the voluntary efforts of the public. In these cases the Association, together with its sister society, "The Royal Society," becomes the spokesman of science with the Crown, the Government, or Parliament—sometimes even through the Home Government with foreign Governments. Thus it obtained the establishment, by the British Government, of magnetic and meteorological observatories in six different parts of the globe, as the beginning of a network of stations which we must hope will be so far extended as to compass by their geographical distribution the whole of the phenomena which throw light on this important point in our tellurian and even cosmical existence. The Institute of France, at the recommendation of M. Arago, whose loss the scientific world must long deplore, cheerfully co-operated with our council on this occasion. It was our Association which, in conjunction with the Royal Society, suggested the Antarctic expedition with a view to further the discovery of the laws of terrestrial magnetism, and thus led to the discovery of the southern polar continent. It urged on the Admiralty the prosecution of the tidal observations, which that department has since fully carried out. It recommended the establishment, in the British Museum, of the conchological collection exhibiting present and extinct species, which has now become an object of the greatest interest.

I will not weary you by further examples, with which most of you are better acquainted than I am myself, but merely express my satisfaction

that there should exist bodies of men who will bring the well-considered and understood wants of science before the public and the Government, who will even hand round the begging-box and expose themselves to refusals and rebuffs to which all beggars are liable, with the certainty, besides, of being considered great bores. Please to recollect that this species of bore is a most useful animal, well adapted for the ends for which nature intended him. He alone, by constantly returning to the charge and repeating the same truths and the same requests, succeeds in awakening attention to the cause which he advocates, and obtains that hearing which is granted him at last for self-protection, as the minor evil compared to his importunity, but which is requisite to make his cause understood. This is more particularly the case in a free, active, enterprising, and self-determining people like ours, where every interest works for itself, considers itself the all-important one, and makes its way in the world by its own efforts. Is it, then, to be wondered at that the interests of science, abstract as science appears, and not immediately showing a return in pounds, shillings, and pence, should be postponed, at least, to others which promise immediate tangible results? Is it to be wondered at that even our public men require an effort to wean themselves from other subjects in order to give their attention to science and men of science, when it is remembered that science, with the exception of mathematics, was until of late almost systematically excluded from our school and university education—that the traditions of early life are those which make and leave the strongest impression on the human mind, and that the subjects with which we become acquainted, and to which our energies are devoted in youth, are those for which we retain the liveliest interest in after years, and that for these reasons the effort required must be both a mental and a moral one? A deep debt of gratitude is therefore due to bodies like this Association, which not only urges the wants of science on the Government, but furnishes it at once with well-matured plans how to supply them with the greatest certainty and to the greatest public advantage.

We may be justified in hoping, however, that by the gradual diffusion of science, and its increasing recognition as a principal part of our national education, the public in general, no less than the Legislature and the State, will more and more recognise the claims of science to their attention; so that it may no longer require the begging-box, but speak to the State, like a favoured child to its parent, sure of his parental solicitude for its well-fare; that the State will recognise in science one of its elements of strength and prosperity, to foster which the clearest dictates of self-interest demand.

If the activity of this Association, such as I have endeavoured to describe it, ever found or could find its personification in one individual—its incarnation, as it were—this had been found in that distinguished and revered philosopher who has been removed from amongst us in his ninetieth year, within these last few months. Alexander von Humboldt incessantly strove after dominion over that universality of human knowledge which stands in need of thoughtful government and direction to preserve its integrity; he strove to tie up the *fascies* of scientific knowledge, to give them strength in unity. He treated all scientific men as members of one family, enthusiastically directing, fostering, and encouraging inquiry, where he saw either the want of or the willingness for it. His protection of the young and ardent student led many to success in their pursuit. His personal influence with the Courts and Governments of most countries in Europe enabled him to plead the cause of science in a manner which made it more difficult for them to refuse than to grant what he requested. All lovers of science deeply mourn for the loss of such a man. Gentlemen, it is a singular coincidence, that this very day on which we are here assembled, and are thus giving expression to our admiration of him, should be the anniversary of his birth.

To return to ourselves, however: one part of the functions of the Association can receive no personal representation, no incarnation; I mean the very fact of meetings like that which we are at present inaugurating. This is not the thoughtful direction of one mind over acquired knowledge, but the production of new thought by the contact of many minds, as the spark is produced by the friction of flint and steel; it is not the action of the monarchy of a paternal Government, but the republican activity of the Roman Forum. These meetings draw forth the philosopher from the hidden recesses of his study, call in the wanderer over the field of science to meet his brethren, to lay before them the results of his labours, to set forth the deductions at which he has arrived, to ask for their examination, to maintain in the combat of debate the truth of his positions and the accuracy of his observations. These meetings, unlike those of any other society, throw open the arena to the cultivators of all sciences, to their mutual advantage; the geologist learns from the chemist that there are problems for which he had no clue, but which that science can solve for him; the geographer receives light from the naturalist, the astronomer from the physicist and engineer, and so on. And all find a field upon which to meet the public at large, invite them to listen to their reports, and even to take part in their discussions—show to them that philosophers are not vain theorists, but essentially men of practice—not conceited pedants, wrapped up in their own mysterious importance, but humble inquirers after truth, proud only of what they may have achieved or won for the general use of man. Neither are they daring and presumptuous unbelievers—a character which ignorance has sometimes affixed to them—who would, like the Titans, storm heaven by placing mountain upon mountain, till hurled down from the height attained by the terrible thunders of outraged Jove; but rather the pious pilgrims to the Holy Land, who toil on in search of the sacred shrine, in search of truth—God's truth—God's laws as manifested in His works, in His creation.

THE LATE MR. BRUNEL, C.E.

By this time the death of Mr. I. K. Brunel, who first started the idea of the Great Eastern, has become known to all of our readers. We abridge the following interesting memoir of the lamented gentleman from the *Illustrated News of the World* of the 25th of March last, (adapting the tense of the article to present circumstances), and we may also inform our readers that with that number of the paper an admirably life-like portrait of Mr. Brunel may be obtained:—

Isambard Kingdom Brunel, Esq., was one of those individuals who have inherited a professional name and professional talents, like the Stephensons and the Herschels, both of whom have been equally distinguished in a second generation for the engineering skill and astronomical science which belonged to their fathers respectively. He was the only son of the late Sir Mark Isambard Brunel, the engineer of the Thames Tunnel, by Miss Sophie Kingdom, of Rouen. He was born in 1806 at Portsmouth, where his father was engaged in erecting the block machinery for the Government Dockyard. Whilst still a child he was sent for his education to France, of which country his father was a native, and studied mathematics and civil engineering at the College, Henri Quatre, at Caen, until the completion of the usual course. He was about twenty years of age when he commenced the work of a practical engineer under his father, who was engaged in the excavation of the Thames Tunnel. It is well known that the progress of that gigantic and amazing work was frequently interrupted by the influx of water from the bed of the river above, and that one or two fatal accidents occurred to the workmen engaged upon it. But it may not be equally well known that Mr. Brunel, on these occasions, was always the last to quit his post, and

only saved his life by swimming—an art in which he was particularly expert. In 1833 the final irruption, as we learn from an article in the "English Cyclopædia," surprised him when he was some six hundred feet distant from the end of the tunnel; he was, however, borne along by the stream, and, not losing his usual composure and presence of mind, he happily rose to the surface near the top of one of the shafts, and so contrived to save his valuable life. The special objects of Mr. Brunel's study were mechanical and railway engineering, and the construction of machinery for locomotives and steam navigation, though he devoted no less than ten years to the experiments made by his illustrious father to test the applicability of carbonic acid gas as a motive power to engines of various kinds. Already, namely in 1830, Mr. Brunel had been elected a Fellow of the Royal Society, mainly on the score of the professional reputation which he had gained in the elaboration of the Thames Tunnel. In 1833 he was appointed chief engineer to the Great Western Railway, then first projected, the whole of which line, including the arches, viaducts, and tunnels, was constructed from his designs or under his direction. Among the most important works in the way of bridges on this line of railway, as well as on its extension branches, may be mentioned the bridge over the Thames at Maidenhead, remarkable for the longest and flattest arches made of brick; and that over the Wye at Chepstow for the great difficulties overcome in its construction; and that over the river Tamar at Devonport, which in span and height is of nearly the same dimensions as the Britannia Bridge over the Menai Straits. In the celebrated "battle of the gauges" he supported the claims of the "broad gauge," but unsuccessfully, against Mr. Stephenson. Mr. Brunel was also largely engaged as a civil engineer upon the construction, remodelling, extension, and improvement of very many of the docks at our largest outports. The most important of these are the Bute Docks at Cardiff and the old North Dock at Sunderland. Mr. Brunel was the engineer and designer of the Great Western steam ship, and also of the Great Britain, and several others of our largest steamers. In 1842 he was employed by her Majesty's Government to construct the elegant Suspension Bridge which spans the River Thames at Hungerford, which has the widest span of any bridge in England. He also took an active part in assisting Mr. Stephenson to float and to raise into their present position the Conway and the Britannia tubular bridges on the line between Liverpool and Holyhead. In 1850 Mr. Brunel had entrusted to his care the works of the Tuscan portion of the Sardinian railway, which he conducted to a successful termination in about three years. During the recent war with Russia Mr. Brunel's talents as a civil engineer were again called into requisition for the establishment and refitting of the Renikoi hospitals on the strait of the Dardanelles. After his return from this task in the East, Mr. Brunel's energies were mainly devoted to the construction of the Great Eastern, which he originally projected jointly with Mr. J. Scott Russell. Mr. Brunel was chosen a member of the Council of the Royal Society in 1844. He was also one of the Vice-Presidents of the Institution of Civil Engineers and of the Society of Arts, a Fellow of the Astronomical, Geological, and Geographical Societies, and a Chevalier of the Legion of Honour.

PATENT MILL-BANDING.—It would seem that we last week were led into an error, in reply to numerous readers, in stating that Messrs. Spills' Patent Mill Banding could be obtained at Bread-street, City. The Government contract works at Stepney Green is the only place, for the present, where it should be applied for, and where the strongest tests of its utility may be witnessed in its practical application to machinery under extraordinary difficulties, purposely designed for such exposition. The retail house in Bread-street has been closed.

WILLIAM ARMSTRONG'S NEW UZZLE-LOADING ORDNANCE.

WILLIAM ARMSTRONG recently obtained pro- under the Patent Law for an improvement le-loading ordnance and projectiles, which describes :—
lised ordnance as heretofore made (other eech-loading ordnance) the loading, owing necessary tightness of the fit, presents practical difficulties, which it is the object invention to avoid. For this purpose I e projectile, fitted with suitable fillets or ons on one side, to enter the piece of e by one end and to leave it by another track, jectile and the piece of ordnance being so to each other as that the projectile on ; and throughout the loading of the piece one shall be free and easy to move, but ring the piece of ordnance shall be itly tight to preserve the steadiness l to precision of action. The projec- addition to the ordinary projections jectiles adapted for rifled ordnance, is d with certain piece or pieces of a soft l, which will crush and prevent any g or too great tightness as the projectile the piece of ordnance." Sir William has eeded to complete his patent for this m.

IMPROVED METALLIC SHIPS.

SCOTT RUSSELL, the builder of the Great , has just obtained letters patent for a ind of metallic ships, designed apparently ate the fouling to which the bottoms of eals are subject. His invention consists in oting the framing of the ship of angle or bars, made of yellow or Muntz's metal; plating the framing with sheets of a like ead also in plating the frames of ships ead of angle-iron, or other bars of iron, ead of yellow or Muntz's metal. The of each yellow or Muntz's metal are to be d to each other and to the framing by f the same metal. The outwaters also, and rn and rudder posts, and other parts of the ; of ships and vessels, as well as the r-les to be by preference of Muntz's or yellow For these purposes it is believed that the mpound or alloy consists of about 60 f the best copper, and 40 parts of the lter; but such proportions may be varied, ll known, within moderate limits. "It is ed," says Mr. Russell, "to construct the f a ship or vessel of the yellow metal, and bime therewith sheets of like metal; but I , experiment ascertained that the particular f copper and zinc above mentioned is so on in its electrical character as not to act thereon when the two are placed in con- sea water, and therefore that in construct- hip or vessel, a frame of iron may advanta- be plated over with sheets of yellow or 's metal, whilst sheets of copper are wholly id for the purpose." Mr. Russell, in his ation of the invention, further says:—
frame of a vessel when of yellow or Muntz's I construct of any convenient form, as iron is employed, and employ a similar sec- metal both in form and size. The yellow ntz's metal is brought to the section re- by rolling, just as is the case with iron, is worked in a similar manner. The stern and other parts, which in iron ships are , I prefer when yellow or Muntz's metal is o cast to form. The plating of yellow or 's metal I make of the same thickness as iron is used, and it is secured to the frame ets of yellow or Muntz's metal, which are l in a similar manner to iron rivets, but care be taken not to heat the rivets too highly, t to keep them heated longer than is neces- When an iron frame is to be plated with or Muntz's metal, it is to be constructed as iron plating were to be employed, and the or Muntz's metal plates should be of a thick- ach as is usual for plating ships with iron.

Either yellow or Muntz's metal or iron rivets may be used, but yellow or Muntz's metal is preferred." It is difficult to see at once the probable bearing of such an invention as this. It would seem, however, that it must either be a very valuable or a very worthless one, and from the known ability of the patentee, it can scarcely be deemed the latter.

THE SAFETY MATCH.

It will be seen by referring to the statistics of London fires during the year 1858, as given in our impression of the 4th of March last, that out of the 1,114 fires forming the total of serious con- flagrations, the following proportion was occa- sioned by the usual contrivances for procuring flame, viz. :—

Children playing with lucifers...	12
Lucifer matches accidentally ignited	7
" " making	3
" " careless use of	17
	—
	39

In the first of these instances the sacrifice of life and wholesale destruction of property were traced principally to the fact of children inserting lucifer matches into various nooks and crevices where an accidental concussion had produced their ignition. The next in the series of casualties are accidents resulting from the sudden ignition of boxes or bundles of phosphorised matches. The necessity as well as the possibility of removing the fatal cause of these accidents has long been felt; and we are happy to introduce to the notice of our readers a contrivance by which such occurrences, which hitherto have led to so many terrible disas- ters, may now be completely obviated. This in- vention, which has reached us from across the Channel, and which has already been adopted in most of the large establishments in Paris and other towns of France, consists of a match which cannot ignite by friction with ordinary substances, but which bursts into flame when struck upon a chemically-prepared substance, owing to the pecu- liar action occurring between the two bodies which are thus brought into contact. Without the prepared strip, the matches may be struck or trodden upon without the possibility of ignition. The advantage of having these articles tipped with a material which is not inflammable *per se* is sufficiently obvious, and we doubt not will recom- mend the "Safety Match" not only to careful housewives, but to the owners of large establish- ments where the ordinary "lucifers" are now used, and, we are afraid, often left carelessly about. The cost of the "Safety Match" is scarcely more than that of its less trustworthy predecessor. It is to be had of Mr. Twinberrow, chemist, 2 Edward's- street, Portman-square, who is the sole agent in this country for the article.

NEW PHOTOGRAPHIC PROCESS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."
GENTLEMEN,—Perhaps you will be kind enough to call the attention of the photographic public to the following discovery.

If some perchloride of iron be poured over a piece of polished copper (such as used by en- gravers) the copper will immediately be affected, and its colour slightly changed. The plate may now be washed with water, and dried with a cloth, when it is sensitive to the light of sunshine. If a negative picture be placed upon it in the ordi- nary way, and it be then exposed to sunshine, in ten minutes or a quarter of an hour a beautiful black positive on a copper ground will be ob- tained. Silver may be used, but not so well.

This experiment establishes the fact of the two substances, copper and perchloride of iron, acting photographically; the facility, too, of obtaining a picture to be engraved so easily and directly upon the copper-plate, will doubtless prove useful to engravers. I remain, Gentlemen,

Your obedient servant,
COLLIER SMART.

Sunderland, 19th September, 1859.

ALLISON'S IMPROVED BORING AND SINKING TOOLS.

MR. RICHARD ALLISON, of Birmingham, engineer, has just completed a patent for improvements in apparatuses for boring and sinking, which he describes as follows :—

My boring head or tool is hollow, and of wrought or cast-iron, furnished at bottom with a series of chisels or cutters inside the tool, and near the end where the cutters are fixed is a valve of india- rubber, gutta-percha, or other like material, the edges of which rest upon a ledge fixed on the in- side of the tool. I fit a door or trap to the side of the tool, the bottom of which is in a line with the valve seat. The top of the tube carries an ordinary bow sling, whereby to connect it to the rope or chain for communicating the necessary motion to the tool. Wooden blocks are fitted to the outside of the tool, to act as fenders, and pre- vent injury from the sides of the well or shaft. For the purpose of raising and emptying the débris from a well or shaft in the course of being sunk, I employ a pump or vessel consisting of two cylinders one over the other, and the upper cylinder capable of sliding inside that under it; the bottom cylinder is provided with a valve opening inwards, and over the top of the upper cylinder there is a similar valve. The cylinders are held in a suitable frame, and are connected to a rope or chain. Upon the pump being lowered, the upper cylinder will fall within the lower, then upon this upper cylinder being raised a partial vacuum will be formed, wherefore the débris, slush, &c., will flow into the lower cylinder, and be there retained by the bottom valve falling back upon its seat, and closing regress from the bottom of the cylinder. A joint in the frame permits of the lower cylinder being tilted in order to empty its contents. My last apparatus consists of a hollow vessel of lead, gutta-percha, or other suit- able material, furnished with valves connected to a valve rod. This vessel is intended to contain muriatic or other acid for burning out or removing chalk, or other matter, in a shaft or well. Upon the vessel being lowered, charged, to the spot where the acid is to operate, the valve rod is raised to let out the contents of the vessel.

Fig. 1 of the engravings (on next page) is a ver- tical section of a boring head or tool, constructed according to this invention. *A* is a hollow cylinder formed of wrought or cast-iron, to the lower part or bottom of which a series of chisels or cutters *B B* are bolted or otherwise attached; *C* is a valve formed of india-rubber or other material, held by a spindle *D*, which slides through a frame *E*. A door or trap (not shown in the draw- ing) is fitted near the bottom of the cylinder for the purpose of clearing out all dirt; *G G* are fenders, which I prefer to form of wood, fixed to the side of the cylinder by screws. *H* is a bow- sling, to which a rope or chain is connected for imparting the necessary motion to the tool.

Fig. 2 is a sectional elevation of a pump or ap- paratus employed for the purpose of raising and emptying the débris from a well or shaft in the course of being sunk. *A B* are two cylinders, which are so constructed that the cylinder *A* shall be free to slide within the cylinder *B*. The lower cylinder *B* is provided with a valve *C*, opening inwards, and carried by a spindle *D*, working through a frame *E*, resting on a ledge formed on the lower part of the cylinder *B*. A similar valve, *F*, to that just mentioned is fitted to the upper part of the cylinder *A*. *G* is a rod attached to the cylinder *A*, and working through a frame or guide *H*, which is jointed or hinged at *I I*, and connected to the lower cylinder *B* at *J J* by bolts and rivets, as shown. *G'* is a stop or washer formed on or fitted to the rod *G*, to regu- late the height to which the cylinder *A* is drawn; *K* is a bow-sling fitted to the end of the rod *G*, to which a rope or chain is attached for working the apparatus.

To remove slush or débris from a shaft or well the apparatus is lowered to the bottom, and the upper cylinder will fall within the lower; the upper cylinder *A* is then raised by the rope,

ALLISON'S IMPROVED BORING AND SINKING TOOLS.

whereupon slush, débris, &c., will be drawn into the lower cylinder *B*. As soon as the upper cylinder *A* is raised to the top of the cylinder *B*, the weight of stuff in it forces down the valve *C*, and the apparatus is drawn up to be emptied. The emptying is effected by drawing the upper cylinder out of the lower, and turning it clear of the mouth thereof as shown at Fig. 4, when the contents of the lower cylinder are poured out.

Fig. 3 is a sectional elevation of an apparatus employed in connection with the invention for burning out or removing chalk or other matter from a shaft or well. *A* is a hollow vessel formed of lead, gutta-percha, or other suitable material; *B C* are valves connected to a rod *D*, the upper part of which is formed with an eye to connect a rope to; *E* is a sling for attaching a rope to lower the vessel. The vessel *A* is filled with muriatic or other acid, and lowered to the bottom of a well or shaft, when there the rod *D* is raised, which opens the valves *B C*, and allows the acid to flow out.

THE POCKET STEREOSCOPIC PANORAMA.

It is surely quite time that something new made its appearance in apparatus for the exhibition of stereoscopic views, now that the taking of such views occupies hundreds, or we may say thousands, of artists, both amateur and professional, in all parts of the world. Not a town or village, river or brook, hill or valley, mountain or plain, escapes the earnest attention of these lovers of nature. Nor is it only with natural objects that our stereoscopic artists busy themselves; they dive into crypts, vaults, and chancels, and attain what appear to be inaccessible heights, to copy the works of men's hands also. No flights of steps are too bold or too long for them to ascend, no galleries too dark for them to penetrate, no steeples or towers too high for them to reach, if not by steps, yet by ladders and ropes, even, as it were, to outvie each other in overcoming the difficulties of their calling, in order to enable us to enjoy whatever is beautiful in form, curious in workmanship, or interesting from historical associations. By the stereoscopic artist's efforts we are taken in the course of a few minutes from one end of the globe to the other, having learned the history and felt the presence of many objects worthy of study. The wonders of Egypt and of the Holy

Land, of India, of America, the marvellous scenery of Switzerland, besides thousands of beautiful spots nearer and dearer to us, are brought before us with all the reality of nature, and rendered as familiar to us as our own homes, and all by the expenditure of a few shillings and a few minutes, which almost every one can spare. It is difficult, however, notwithstanding all that has yet been done, to determine the ultimate scope and utility of this new and astonishing discovery of stereoscopic art. Whether for amusement or instruction, its capabilities appear perfectly boundless. As a direct means of education it has as yet been comparatively little used, although peculiarly suited for such a purpose. There is scarcely a branch of scientific instruction which it could not be made effectually to illustrate and promote, rendering what would otherwise be most expensive, and beyond the reach of all but a very few, quite easy of possession—namely, correct illustrations of the objects studied. Natural history, in its largest sense, sculpture, architecture, history, physical geography, the manners and customs of nations, antiquities, and indeed every inquiry in which the forms of bodies or their disposition are concerned, may be illustrated in a manner in no way surpassable by means of stereoscopic pictures. What we seem to require is, that artists should set themselves to work to complete judicious series of views in each of the above-named or other departments of study; and, this done, we have in the apparatus we shall presently describe, all that is necessary in order to render stereoscopic views amazingly popular as ordinary means of education. The apparatus we refer to, and of which we append illustrations, is intended to facilitate this work by affording the means of grouping together in the most convenient form stereoscopic views relating to any special subject, instead of mounting them in the ordinary and disconnected way in which they have been hitherto presented to us. The apparatus is of the most simple kind, and in every respect most complete, occupying very little space, so as to be easily carried in the pocket, although containing, if required, as many as a hundred views, or even more, besides the stereoscope itself. Its manipulation is also of the simplest kind, and consists in turning the thumb-screw placed on one side of the case, by which movement the views are successively brought under the eye-glasses. When the apparatus is not in use, not only the stereoscope but the case containing it, as well as the views, collapse and shut up into the form shown in the smaller illustration of what is termed the "box" form. The other wood-cuts represent a modified arrangement of cylinder cases united together by a very ingenious system of bars or lazy-tongs, which expand or collapse as required, placing the cylinders either close together or far apart, so as to exhibit a view between them. The stereoscopic pictures are printed upon the thin French or German paper, and mounted upon silk manufactured for the purpose, which enables them

to be wound upon small rollers, which by suitable means are slightly retarded in their motion, so as to strain the silk band and render the views perfectly flat when under view. This strain upon the silk band necessitates some contrivance, also for keeping the rollers at a suitable distance when being examined, and this is very ingeniously

BOX CASE (Closed).

BOX CASE (Opened).

CYLINDER CASE (Closed).

CYLINDER CASE (Opened).

managed by making the sides of the stereoscope fill up, so to speak, the opening between the two halves of the box casing, or the two cylinders in the modified arrangement. In this latter case the sides of the stereoscope are hinged to the system of bars or lazy-tongs connecting the cylinders, but instead of the sides being hinge

at their lowest parts or edges, the hinges are attached about half or three-quarters of an inch from this point, so that this small portion of the sides descends, while the main part of the stereoscope is raised up, such descending portions locking in between the two cylinders, and so resisting any attempt to bring them together until the stereoscope is lowered for the purpose of shutting up the apparatus. The cases are, we understand, now being manufactured in large quantities both in fancy leathers and woods, papier mâché, metal, vulcanite, glass, and other materials, and we doubt not will take well with the public. The invention is that of Mr. E. E. Allen, of Parkside, Knightsbridge; the dies for the bars of the lazy-tongs having been made by Mr. Hobbs, at his well-known lock factory in Islington. The rivets for uniting them have also been manufactured by him, and the bars stamped out by means of the excellent machines employed in the manufacture of locks, of which some day we hope to find time to give our readers an account. In carrying out this invention Mr. Allen has called to his aid the leather-workers and glass manufacturers of London, the papier mâché makers and brass drawers of Birmingham, the lense grinders and spring makers of Sheffield, the silk and paper manufacturers of France, the vulcanite manufacturers of America, besides the kindly assistance of Mr. Hobbs, who undertook the stamping and rivet making part of the work from the interest he felt in the success of the invention, and knowing the great difficulty of getting anything new satisfactorily manufactured. To Messrs. Jennens and Bettridge also Mr. Allen expresses himself much indebted for their kind co-operation in the manufacture of papier mâché work.

THE ABRIDGED SPECIFICATIONS OF PATENTS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In your abridged specifications of patents you state that the invention of W. and W. McNaught, No. 98, 1859, is not described apart from the drawings. I think it is a mistake, for there was a specification sent along with the drawings containing description and claim.

I remain, yours respectfully,
W. T. C.

P.S. I enclose my card.

Rochdale, September 15th, 1859.

[What is meant by saying that inventions are not described apart from the drawings, is merely that no verbal description, except that in which reference is made to the drawings, is given.—*Eds. M. M.*]

VERTICAL FIRE WITH ARROWS OR BOLTS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—The employment of arrows for vertical fire, as put in practice by the Chinese in the defence of their forts during the late disastrous attack by our sea and land forces at the mouth of the Peiho river, will excite some discussion on the merits of such vertical fire; and as the flight of an arrow shot from a Chinese bow does not exceed two hundred yards, I beg to state that I was in the habit of shooting a bolt from a horse-pistol of the "Brown Bess" bore by vertical fire at Cork, about seven years ago, to the distance of more than four hundred yards. The weight of the bolt was, with its iron head, between three and four ounces. The cartridge was attached to the inner end of the bolt, and did not require to be opened previous to insertion. The head of the bolt projected an inch or two from the muzzle of the pistol, and its shaft being the full length of the barrel caused it to form its own ramrod. I made the above experiments to prove that the guard of a railway train could, from the rear of the train, throw a whistling or explosive bolt high over the head of the driver of the engine, and thus give him warning when required.

I am, Gentlemen, yours, &c.,
J. NORTON.

Rocherville, 19th Sept., 1859.

THE GLOUCESTER CORPORATION DRINKING FOUNTAIN FILTER.

THE GLOUCESTER CORPORATION DRINKING FOUNTAIN.

We are indebted for the following letter to the Secretary of the Metropolitan Free Drinking Association. The description of the apparatus devised by the writer for Gloucester, may be of use in other towns:—

SIR,—Having been instructed by our corporation to prepare a design for free drinking fountains for this city, with the desire of escaping from the stereotyped absurdities of pure water vomited from lions' heads, &c., I had a figure modelled by Mr. Irish, a resident sculptor, representing a child playing at a well—a photograph of which, together with a photograph of the original sketch, showing recess, &c., I enclose. The design is now being carried out in cast-iron (bronzed), and the whole cost, including the fixing in wall, and laying on the water from the main, has been tendered for at £8 8s. each.

I have also purchased a filter, drawing of which I enclose, to act under pressure, a specimen casting of which I have been for the last week experimenting upon, and find it to act (delivering half-a-pint in ten seconds) admirably. You will notice the reverse action, from the top downwards, for cleansing. Each inlet and outlet has a tap on, and by means of the tap in the principal inlet the pressure and the quantity to be delivered may be easily regulated. You will notice, also, that this filter may be placed beneath the flags under the fountain, and covered by a small casing similar to that of the stop-cock casings on water services. By closing the stop-cock on the lower or main inlet, and opening the cleansing cock, the rising tube to the fountain may be emptied in times of severe frost. The cost of the filter, including fixing, &c., will not exceed 50s. The whole cost, therefore, of the fountain and filter, exclusive of drain to the sewers, will not under ordinary circumstances exceed eleven pounds.

Your obedient servant,

JOHN HARVEY,

City Surveyor and Chamberlain, Gloucester.

E. T. Wakefield, Esq., Hon. Sec. Free Drinking Fountain Association.

Gloucester, May 24th, 1859.

Reference to Engravings of Filter.

Figure 1 is a plan, and figure 2 a section through A B of figure 1. The taps at C and D are turned on for the ordinary action of the filter; and the pressure (and therefore the stream of the fountain) is regulated by the tap C. P M is the pipe from the main; I is the inlet; O is the outlet; C I is the cleansing inlet; C O the cleansing outlet; P F is the pipe leading to the fountain; W P is the waste pipe. The teeth or rings shown in Fig. 2 are intended to hold the sponge and sand between them, so as to prevent the

water from passing around the sponge and sand. The plate at the top is pressed down by a screw, to keep the sponge and sand properly compressed.

THE CARBON GAS FIRE.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Several patents have been taken out "for gas fires in open grates," the patent being for the material used, such as "pumice," "asbestos," the material called the "polytechnic fire," "lump asbestos," and other material, the use of which is very limited in consequence of the expense. The "lump asbestos" is valued at a guinea a pound, and the "polytechnic fire" material, although not so expensive in itself, requires more gas to get up a red heat; it also becomes very brittle by use, so that when taken out of the grate to clean the gas-pipes, the holes requiring broaching occasionally, it breaks in pieces, destroying the effect intended. Finding this to be the case, and yet anxious to introduce gas-fires, I have been trying experiments with material of various kinds, and have succeeded in producing a gas-fire superior, I believe, to any yet introduced. I have taken out no patent for it, that all gas companies whose interest it is to introduce gas-fires to the public may do so at the cheapest possible rate. The material I find best suited for use is the carbon—removed by the process called scurfing—from gas-retorts; it should be broken up in lumps of about 2½ or 3 inches, and piled in the grate by hand, not thrown on in a mass. I find this material absorbs the gas, and causes a perfect combustion, making an excellent fire, and throwing out a great heat, with a less consumption of gas than any other material. Gas companies can sell the carbon at 2s. 6d. per bushel ready broken, so that the cost of the material will be trifling, one bushel lasting from three to six months, according to the heat required.

I am, Gentlemen, yours faithfully,
MAGNUS OHRREN, A.J.C.E.

Gas Works, Sydenham, Kent, S.E., Sept. 19th, 1859.

SCREW SHIPS OF WAR.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Could not the screw of a ship-of-war be surrounded by a grating which would protect it from the debris of falling masts, &c. The grating might be placed at such a distance as not to hinder the flow of water, and still be a sufficient safeguard.

I am, your obedient servant,
TRIAL.

Mr. Newall passed through Malta for Alexandria this week, to lay a telegraph cable from Egypt to Turkey, and another across the mouth of the Adriatic. When finished this line will connect the Red Sea telegraph with England.

DR. HOPKIN'S THEORY OF A CENTRAL FIRE.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—It appears natural for the common mind, so soon as it has become acquainted with any phenomenon, to set about and try to account for it, and to build thereupon facts which are but slightly corroborated. Thus as to the fossils found in coal strata, they look like vegetables, therefore they must once have been growing upon the surface of the earth. So of Dr. Hopkin's theory of a central heat (in your last number, p. 183), it has been found that the heat increases in a certain ratio, and must, at a certain depth, become red hot. Yet with only this single fact to support so large a theory, were there no other way of accounting for this increase of heat, it is not unreasonable to give our assent to it. But if it can be found that this increase of heat may be accounted for on principles to which assent will be at once yielded as being open and easily comprehended, then, I think, our assent may not reasonably be withheld—the former set aside, and the latter adopted. I think this heat found in mines may be accounted for in the same way as some other natural phenomena—the heat of the human body and of hot wells. Before constructing any new theory from isolated facts, it would be well to look round us, and see whether any question arising upon them would not be settled by reference to some already-known law of nature—which "acts by general, not by partial laws." One general law is that all substances on passing to a more solid state give out their latent heat, which at once becomes sensible; part of the air drawn into the human lungs at every inspiration becomes a solid or more dense fluid, and the latent heat required, in its aëriform state, is converted into sensible heat, giving life and warmth to the body. Part of the water passing through calcareous rocks, as Dr. Hopkins says, of low conductive power, becomes solid, filling crevices in the rocks, forming stalactites in the caverns, and giving out its latent heat, which becoming sensible in the water passing on is the cause of our hot wells. So water percolating through coal and other strata ultimately becomes wholly solid, and must give out its caloric of fluidity to the surrounding strata, which is, perhaps, the heat we find, and which has given rise to the notion of a central fire.

I am, Gentlemen, your obedient servant,

T. L. H.

19th Sept., 1850.

THE NAVIGATION OF THE AIR.

The navigation of the air—a subject respecting which many of our readers entertain very sanguine expectations, and in reference to which very much has doubtless to be discovered, and as much done—is ably and usefully discussed in the following letter which appeared primarily in the leading journal the early part of the present week. The principle from which the writer starts is, that if we are ever destined to navigate the air it will be by a strict adherence to the principle and a close imitation of the means which have been designed by the Creator for effecting the same purpose in flying animals. He proceeds as follows:—

Be it observed, then, that none of these animals are lighter than the air; on the contrary, their being heavier will be found to be a necessary condition of their flight. It is from their weight that they derive momentum, and without momentum they might float but they could not fly. We sometimes speak of a bird's flight being "buoyant," but this is only a mode of expressing the greater facility with which some birds fly as compared with others. No bird is ever for an instant "buoyant" in the literal sense of that word. Gravity never for a moment ceases to act upon its body, and on the slightest accident the force of gravity brings it heavily to the ground. The sustaining power

in the flight of birds is the energetic action of their wings upon the resisting medium of the air. The comparative power of flight in birds depends on the proportion between (1) their weight, (2) the atmospheric area covered by their wings, and (3) the force with which the wings are worked. It is not the lightest bird with the largest wing which flies best or fastest; on the contrary, the flight of such a bird is generally laborious and heavy. The heron is a familiar example. Its body is extremely thin and light, its expanse of wing is enormous. Every one must have observed how slowly and heavily it flies. On the other hand, birds of the greatest weight, with the *minimum* size of wing which is compatible with flight at all, fly with enormous velocity. The divers are an example. Their wings are very small, mainly used as fins or paddles under water. The weight of the bird is very great; they have, consequently, much difficulty in rising into the air at all, but when once "under weigh" they go like an arrow. It is their great weight, and consequent momentum, which gives them this velocity. To counteract the great force which gravity exerts upon them, or rather to turn it into a horizontal instead of a perpendicular direction, the small wing is worked with almost inconceivable force and quickness. Nothing but the most rapid strokes could derive from so small an atmospheric area sufficient supporting power. Between these two extremes—the heron and the diver—there is among birds every variety of proportions between weight, area of wing, and flapping power. Each different proportion gives a different kind, and a varying power of flight. Some proportions are best adapted for "buoyancy," others for velocity, others for facility of direction. The power of flight, in all its combined conditions of lightness, duration, and perfect facility of direction, attains its *maximum* in some species of the swallow tribe, especially the "swift;" and in various kinds of sea birds whose wings are of very similar construction. The soaring of some birds is an apparent exception to the ordinary action of flight, and suggests to the eye the idea of actual buoyancy or floatation. But the exception is apparent only. The eagle or the vulture, when soaring, is not the less a very heavy bird, and the slightest derangement of his machinery of flight would bring him crashing to the earth. Weight is as essential to soaring as it is to progressive flight. The soaring of a bird is effected precisely as the same action is accomplished in a boy's kite.

This being the principle of flight in birds let us look for a moment at the means or machinery provided to satisfy these necessary conditions. A whole volume might be written on the structure of the wing in birds. In the whole range of nature there is no more beautiful piece of mechanism. But there is one main feature in its action which above all others deserves attention. The stroke of a bird's wing is always perpendicular, and this one action serves both to sustain and to propel. This is a result as well of the structure of the whole wing as of the structure of each feather. The feathers are all so placed with reference to each other that in the upward stroke they tend to separate and to allow the air to pass between them; while in the downward stroke they are pressed against each other so as to present to the air one impervious expanse, and thus to secure the greatest possible amount of atmospheric resistance. The same purpose is further assisted by the shape of the whole wing, which is slightly convex above and concave below. But beautiful as this mechanism is, the most beautiful part of the structure remains to be noticed—viz., that which converts the stroke for sustaining into a stroke for propelling also. This is a result of the structure of each quill, and of the direction in which all the quills are set. Each quill is highly elastic in substance, and in form tapers rapidly to the end. All the quills are so set that the elastic ends constitute the terminal and posterior margins of the wing. The anterior margin of the wing is rigid—being that containing the bone in which the quills are set. The consequence of this arrangement is, that the air,

compressed by the downward stroke, escapes backwards, bending upwards in its passage the fine elastic tips; and thus exerting an upward and onward reaction on the whole body of the bird. It must be added that the same principle is followed in the wings of all flying animals; with much variety in the material, form, and disposition of parts. The wing of the bat is the most conspicuous modification—the more remarkable as in all probability it is on this model that artificial wings will be most easily constructed. By means of a leathery web stretched between long, attenuated, and elastic bones, the fore-legs and fingers of a mammal are made to perform precisely the same functions as the pinions and quills of birds.

The problem of aerial navigation will never be solved until the principles of flight are clearly understood, nor until we recognize precisely what are the obstacles which prevent us from acting upon them by artificial means. It is, of course, possible that these obstacles may prove to be insuperable. I entertain a different impression, but, at all events, they cannot be overcome until they are exactly known. I believe them to be all summed up in one great deficit of our present mechanical knowledge—a light motive power. Steam is the greatest motive power among all that we know of yet, but the material required for the generation of steam, and the material required for the construction of its machinery, render it enormously heavy. We don't want buoyancy, but neither can we succeed with excessive weight. Every year is, indeed, adding to the perfection of the steam engine—to its compactness and to the amount of power which is derived from a given volume of steam. It is difficult to say what economy of weight might not be effected if ingenuity and science were specially directed to this object, and if the cellular structure adopted in the bones of birds, and which is already receiving so many new applications in mechanics, where strength and lightness are required, were applied wherever it is possible. Still, I have very little hope that, until a lighter motive power than steam is discovered, aerial navigation will be accomplished. But even with steam some experiments might be tried which would test the principles of flight, and at least lead the way in a right direction for the progress of discovery.

Not being myself a practical mechanic or engineer, I would suggest for the consideration of others some of the conditions under which such an experiment might be made. I assume that it would be easy to derive from a steam engine the perpendicular action of a bird's wing. In truth, the direct action of a piston would give this movement. I rather think this is the simple principle of Nasmyth's steam hammer. Would there be any difficulty in making such a piston work a pair of wings, constructed on some such model as the wings of a bat? What is the *maximum* velocity with which such a piston could be made to work a given area of wing? or, conversely, what is the *maximum* area of wing which such an engine could be made to work at a given velocity.

When these questions have been answered by calculation or experiment, the next step would be to ascertain the lifting power of such action. I have no hope that any steam engine can be made so light and so powerful as to work wings capable of lifting its own weight. But the important question is—*How much* of that weight can be so lifted, or rather (as no actual lifting would take place) how much of the weight would be deducted from the gross weight by the rapid action of the wings? Would it be any appreciable quantity? It is impossible to doubt that the amount of atmospheric pressure exerted by steam power working a vane or wing would be very considerable. The amount of such pressure would be the measure of the lifting power exerted, and might be tested or calculated in various ways.

Supposing, then, that a steam-engine could be constructed which could move wings equal to lifting 1-10th, or even 1-20th of its own weight, the difficulty remains how to deal with the re-

mainder. In default of any other means of dealing with it, I would suggest that it be balanced by the lifting power of a balloon. In this combination, be it observed, the whole machine would not be buoyant. Even this modified use of a balloon is open to great objections, because the power exercised over it by the slightest current of air would be very great, and the experiment could only be tried in a tranquil atmosphere; but, in default of any machine capable of lifting the whole of its own weight, there seems to be no alternative but to take off part of that weight by a balloon. My belief is that such a machine, when its wings were put in motion, and when it rose from the ground, would be found capable of being directed, and that the direction of its flight would be determined by that in which its wings were set.

I have said that the wing of a bat would be found most easy of imitation. There is, however, one observation of great importance which may be gathered from the flight of different animals—viz., that, as regards facility of flight, the shape of a wing is even more important than the largeness of its area. Length is more important than breadth. Birds which possess the greatest powers of flight have always very long, but often very narrow wings. The swift swallow is an excellent example. Every one must have observed the extraordinary narrowness of its long wings. This peculiarity is carried to its extreme limits in the wings of the albatross, a bird of unwaried power of wing. The cause of this result is pretty obvious. Length gives leverage, and leverage is, of course, all-important in lifting power.

In a subsequent letter Mr. L. Morris writes as follows:—"It may be useful to point out a few errors into which he (the above writer) has fallen, and which can only have the effect of leading away from the path he wishes to pursue. He states that weight is essential to a bird's flight, as producing momentum; now this cannot be considered as essential, but as incidental. A kite is not sustained by the weight of the string, but in spite of it, although the string is incidental to its condition. We do not, in order to overcome the power of gravity, require an aerial machine to be proportionally heavy; on the contrary, the lighter it is the better. The writer also states that a bird is enabled to fly more swiftly and with greater ease in proportion to its increase of weight (within certain limits), when it must be evident that both the swiftness of its flight, and consequent momentum, entirely depend upon the speed with which the wings are moved, and its rate of progress can never exceed the rate of this movement. Your correspondent also observes that the 'soaring' of a bird is caused by the pressure of the wind on its outstretched wings, exactly as in the case of a kite. This action of the wind, however, could only produce a backward movement, and 'soaring' is evidently caused by the previously-acquired movement of the bird causing a resistance which for a time sustains it in the air; and this is the very principle carried out in previous attempts to construct a flying machine. It is sufficient to sum up by stating that the problem of aerial navigation will be easily solved whenever the progress of science shall place us in command of a motive power considerably lighter in proportion to its capacities than any steam-engine that can be constructed, and not till then. This is the true direction to which our aims should tend."

THE NEW STEEL.

We have this week had an opportunity of examining a sword-bayonet constructed of steel manufactured by Farrar's new process. This sword-bayonet has been put through all the tests ordinarily used to try such instruments, and has stood them with perfect success. The steel commonly used for such bayonets by the manufacturers of the weapon cost £81 per ton, whereas the Farrar steel employed in the present instance costs only about a third of that amount per ton. The value of Mr. Farrar's process may be judged of from these facts.

THE ASSOCIATION OF FOREMEN ENGINEERS.

On Saturday night last the anniversary dinner of the "Association of Foremen of the Engineering Trade" took place at their rooms, 36 St. Swithen's-lane, City. At seven o'clock Mr. Newton, of the Royal Mint, who, it may be remembered, was elected chairman in place of the late Mr. Sheaves in January last, took his seat at the head of the table, and was supported by from eighty to ninety members and friends of the society. After dinner the usual loyal and complimentary toasts were drunk, being severally prefaced by brief but appropriate and able speeches from the president. In giving the "Prince Consort and the rest of the Royal Family" the chairman took the opportunity of saying that H. R. H. never distinguished himself more than when at Aberdeen the other day he paid homage to the votaries of science, and acknowledged himself a devotee at her sacred shrine. "Our Employers" was the next toast of the programme. The chairman in proposing this said he considered it to be a toast in which every individual member of the association must feel a direct and personal interest. It was not necessary to urge the complete and indissoluble identity of interest which existed between masters and foremen engineers. Not one among their own body would think of disputing such a position. "We one and all" said he, "are aware that employers cannot fail without foremen feeling the effects of their failure, and that in their prosperity is bound up our own fortunes." He must be permitted to say, however, that from the attitude assumed by engineering employers generally towards the Foremen's Association, he was afraid that they did not regard this intellectual, moral, and charitable union with the favour which it had a right to expect at their hands. It was certain that the masters' advantage was bound up in the welfare of those who served them, and it was unfortunate that so much coldness should be manifested towards a society such as that over which he had the honour to preside, by employers generally. Would that employers would attend their monthly meetings and learn from their own observation that their's was no unfair banding together for the purpose of coercing the labour market, but simply a union for mutual improvement and for provident objects. Would that an employer occupied to-night the chair he so unworthily filled! Mr. Newton then proceeded to say that he trusted from henceforth the Association of Foremen Engineers would emerge from the dark cloud which seemed to obstruct the vision of employers, and that the latter would join the society in large numbers as honorary members. He appealed to the representatives of the scientific press then present to put before employers into whose hands their journals fell, the views of the members of the association, and to incite them to lend their countenance to those who earnestly desired their friendship and co-operation.

Mr. Fowler, an employer, in responding to this toast, disclaimed to some extent the strictures of the chairman as to the isolation of employers generally from the interests of the society, and concluded by handing in his own name and subscription as an honorary member.

"Honorary Members and Supporters" was the next toast, and this was responded to by Mr. Blackett.

"Prosperity to the Association of Foremen Engineers" now claimed the attention of the assembled members of it, and the chairman having expressed his views of the importance of the institution, and his confidence in its permanent well-being and increasing usefulness, called upon the secretary to furnish from his minute book the substantial reasons he had for forming those conclusions. Mr. Jones then proceeded to read an abstract report of the society's rise, progress, and present prospects, the substance of which we subjoin:—

"Sir, I have the satisfaction of presenting in compliance with your request, a brief history of the Association of Foremen Engineers, with some account of its present financial condition. In the year 1852 several members now present, together with Mr. Sheaves, now, alas! no more; Mr. Allison, whose unfortunate accident we all deplore, and myself, first met to discuss the desirability of forming an association of foremen of the various branches of the engineering trade. The matter was fully considered on these occasions, a committee was formed, meeting nights, once or twice in each week, were appointed in order to frame rules and to make regulations, and ultimately from those small beginnings grew into existence the now flourishing society of which we are all so proud. It must, however, in justice to the memory of our late lamented chairman, be admitted that the idea of such a society originated with himself. The following brief statement will enable our

new members and friends generally to trace the course of the association since that early period of its history, and to understand its present numerical and financial condition.

"Having thus shown you a copy of the whole of our receipts and expenditure as well as the number of members in each year of the existence of the society, I think that you will be willing to admit that we have not been associated for an idle purpose. Our funds have been made available on all legal occasions for the assistance of members, whilst they have solaced the widows and orphans of such as have departed to that bourne whence no traveller ever returns. It may be further stated that during the present year valuable papers have been read at our ordinary monthly meetings by Mr. Newton, our chairman, on 'The Influence of Mechanical Science and Mechanical Men on the Age in which we Live.' By Mr. Keyte, on 'The Making of Heavy Iron Castings.' By Mr. Briggs, Senr., on 'The Concussion of Water.' By Mr. Stabler, on 'The Economical Formation of Steam.' And by Mr. C. F. Hayes, on 'The Manufacture of the Rifle.' These and the discussions which followed them have tended in no small degree to the elevation of the institution, and the edification of its members. The library fund, a separate and distinct affair from the general fund, I regret to say languishes somewhat, and though we have to thank Mr. McGregor especially for a donation of books, yet the library is not quite what it ought to be. I think, Mr. Chairman, that the report may be deemed on the whole satisfactory, and I look confidently forward to the future of the 'Association of Foremen Engineers.'"

The reading of this statement elicited much applause, and silence being restored, the chairman proceeded to give, as his next toast, the "Scientific Press." Alluding to the statement of the secretary, and trusting that the representatives of the press then present would ensure it the publicity of their columns, Mr. Newton proceeded to observe that much of the recent success which had attended on the society was due, as he thought, to the notices of their monthly meetings, which had been regularly published in the various journals which constituted the scientific press of London. In eulogistic terms the chairman then gave the toast, which was drunk with "three times three." In obedience to the request of the chairman, Mr. E. J. Reed, of the MECHANICS' MAGAZINE, as the senior member of the press present, responded to the toast. In his address Mr. Reed alluded to the importance of the class of men who constituted the foremen engineers of the kingdom. He pointed out the unrecognised influence which they exerted in the promotion and successful carrying out of all engineering works, and incited them to persevere in the pursuit of mutual improvement for which the association offered such facilities.

"Success to the Engineering Trade" succeeded, and Mr. Keyte acknowledged it. Then came the "Founders

of the Association," and a response on behalf of the surviving founders by Mr. Briggs. "Our Visiting Friends," prefaced in a kindly tone by the chairman, was drunk, and Mr. Robertson, in a talented speech, acknowledged the honour conferred. The "Health of the Chairman" was next proposed by Mr. Keyte, who described that gentleman as "an able mechanic and a clever man," which he said well qualified him for his post. This was received with an amount of enthusiasm and of what are called "musical honours," which must have amply repaid the chairman for his exertions on behalf of the society. The cheers for Mr. Newton made this part of the proceedings quite an oration. Under the manifest influence of strong emotion, the chairman thanked the assembled foremen for the warmth with which his name had been received, and promised to devote his whole energies to the welfare of the society. He regarded, he said, mankind as the agents of a higher Power, and bound, therefore, to develop the good promptings of the mind into deeds of kindness and love. Gratefully he returned his warmest acknowledgments, and proud indeed was he to possess their good opinion. The health of the secretary was next proposed by Mr. Ross, and duly responded to by the former. The health of the treasurer was pledged by Mr. Keyte, and the "Managing Committee and Librarian" was proposed as a toast in a neat speech by Mr. Stahler, Mr. Briggs returning thanks. Mr. Sutfield gave "The Ladies." These pleasant proceedings, un-mixed by one dash of alloy, brought twelve o'clock too speedily, and the National Anthem concluded a delightful meeting.

It may be stated that the address of the Secretary is 7 Arlington-square, New North-road, Islington, London, and that country foremen are eligible as members.

Our Weekly Gossip.

In searching the annals of the coinage of Great Britain some curious facts have been disinterred from musty volumes and age-worn parchments. Few persons probably, for instance, are aware, as we were not until lately, that the term "bawbee," as used by our northern friends, was the legitimate name of a current copper coin once circulating beyond the Tweed. Towards the end of the reign of Charles II. this coin came into existence, and passed for sixpence. The "bawbee" had for its obverse impression the King's bust facing his right, His Majesty's name abbreviated, numeral and titles; and for its reverse, *Nemo Me Impne Lacesset*, and the date 1677, with a large thistle crowned. The weight of the "bawbee" was about 130 grains. Coins called "bodles" had circulated in Scotland before the period in question, but Charles II. seems to have had a penchant for creating new coins, and for giving new impressions to them, he therefore ordered "bodles" to be struck equal in value to twopence only, in place of three-pence, as previously. The "bodle" of this monarch bears a similar device as an obverse to that on the "bawbee," with a sword and sceptre under a crown, and a reverse similar to that of the "bawbee," except that the thistle is not crowned. The weight of the "bodle" is about one third that of the "bawbee."

It is a curious fact, and somewhat apropos to the coming coinage of mixed metal, that the *Merris Monarch* had a peculiar horror of mixed materials for coinage. It was ordered, for example, in the year 1661, that "three thousand stone weight of pure copper, without any mixture of brass," be forthwith coined for circulation in Scotland. "Two thousand stone weight of said copper to be coined within three years after the date hereof, and the third thousand within such time after the expiration of the three years as the Lords of the Secret Council shall judge meet, and who are to resolve upon the impression and circumscription to be stamped upon the pieces." When will the "Lords of the Secret Council" of our own time come to a decision as to the "impression and circumscription" to be put upon the new bronze pieces which the Government have determined to issue. It is rumoured that there are great differences of opinion among them on the point, and that a strong determination is manifested in one quarter to keep Britannia, King Charles' Lady Stewart, seated as of old upon the rock supposed to be on the sea shore. We still hold that public competition among artists and engravers is the proper course. Has no engraver the public spirit to produce a set of designs for the mixed metal pence, halfpence and farthings? Speaking of the Scottish coinage, it may be stated that in the reign of James II. no copper coins were issued; that in the reign of William and Mary more "bawbees" and more "bodles" were coined, the first having on the obverse the busts of the King and Queen, and

their names, and the second on the obverse the initials of their majesties in cypher in the field, instead of the sword and sceptre, and only their titles circumscribed. The last distinctive copper coins for Scotland were struck during the reign of William III., and bear date 1694, and no "bawbees" or "bodles" have been minted since that time.

A French agent, who is stated to be a distinguished naval officer, pre-eminent for his nautical knowledge and experience (and whom, we believe, to be Admiral Paris, *Major-General Maritime* of the port of Brest, and with whom we had much pleasant and instructive intercourse on board the *Great Eastern*), bears testimony, in a letter published in Wednesday's *Monitor*, to the enormous strength and indubitable safety of the *Great Eastern*, and to her victory over the ocean. With regard to the first point, the naval officer says: "Nevertheless, it may be said that the destruction of the forward funnel of the *Great Eastern* might have happened to the smallest steamer, and would probably have occasioned its total destruction, because it would not have presented the mass and solidity of the great ship, while the accident in question in nowise compromises the future of this last." With respect to the second point, the same authority says: "The little swell while going against a strong head wind, and a heavy sea on, proved that the nautical problem has been solved (the italics are his own). If there be any doubts, they can only be as to her rolling, because she experienced no slanting heavy seas, and the vessel was too light to be considered in her normal position. But when, with the wind right ahead, she oscillated up and down hardly a quarter of a degree, while the neighbouring vessels plunged into the waves, and her sharp bows threw up less spray than a boat, one feels convinced that no sea can stop her, and that she cut through the waves with too great a force and facility for them to retard her progress, or for them even to produce that pitching which is so inconvenient to passengers. Contrarywise to so many ships of rounded lines, which the sea tosses and retards more than does the wind, the *Great Eastern* meets with no impediment from the waves. She cuts them too easily to feel their rapid motion; the wind appears the only obstacle which nature can present; and all who are acquainted with navigation know how slight its action is in comparison with the action of the waves. Thus the trial which has just been made proves that this gigantic mass will always overpower the sea, and that she will not feel even the effects thereof, except when the waves strike her sideways. But then, again, the weight of the vessel and her length will diminish her motion, as was proved during the voyage, when, from the breaking of some part of her steering gear, she was thrown into a position to present her broadside to the sea."

The following clever piece of vaticination, taken from a leading article in the *Times*, is well worth reading:—"A thousand years hence, if the world last so long, we shall have 'Railway Antiquities.' At the meetings of perambulating associations papers will be read on the origin and early struggles of this or that line. The sketches of a primitive locomotive will then be as curious as the picture of a Chinese junk or the Royal Harry, in which Henry VIII. set forth to the Field of the Cloth of Gold. Bits of old rail will be handled and passed to and fro, with remarks on the quality or make of the iron. Here and there a bridge or a viaduct will be shown to illustrate the waste of material natural to a semi-civilized age, and the preference of finery to simplicity. Architects will remark on the absurdity of our making a railway train pass over a Doric entablature, or placing a booking-office under the Temple of the Giants. Should there ever be discovered a means of locomotion sufficient to scale greater inclines than are now possible, our prodigious tunnels, cuttings, and embankments will then be as mere curiosities and as decided proofs of our scientific ignorance as the aqueducts of Rome. They will be classed with pyramids and sphinxes, as the mere follies of power and wealth. Nevertheless, the earth-work will stand. It will never answer anybody's purpose to level a huge embankment or fill up a cutting. Costly as it was to make, it will be more costly to unmake; there will be no object, and the funds will not be forthcoming. So, should the world last a thousand or ten thousand years, 99 per cent. of our earthworks will stand just as they are. So stand the barrows, and dikes, and hill-camps, which are uncertainly referred to Britons, to Romans, to Danes, and every tribe that existed before the Conquest. Stones are removed, marble is burnt for lime, ashlar work is stripped away, even concrete crumbles, the copper tie attracts the plunderer, everything perishes or is destroyed, but solid earth remains. There it lies; it neither moulders nor rusts; nobody carries it away; it is neither blown up nor ploughed over; earth it was, earth it is, and earth it will remain. So, as we say,

ten thousand years hence our railway earthworks will remain. There will then be a hundred thousand miles of rail, and every village will have its branch; and there will be a series of *Bradshaws*, with their maps complete, purchased at the rate of $\frac{1}{2}$ a number, in the British Museum, and there will be no difficulty in distinguishing an ancient line of 1859 from the modern addition made in the reign of Albert XXIII., A.D. 6859. A single peck of the mound will show the difference of the soil, and the production of a time-table will set at rest the question whether or not there was a line in the 19th century between one place and another. Many laments will be made over the unhappy convertibility of paper, which will then have reduced so many interesting records to the original pulp. Even a palimpsest, it will be observed, can be made to reproduce its six or seven strata of ancient lore; but piles of journals, archives of railways, *Harpers* and *Bradshaws*, pulp they were, and into pulp will they have returned."

The *China Telegraph* communicates the following facts respecting telegraphic progress. Messrs. Newall and Co's steamers *Imperator* and *Imperatrix* will be ready to leave Liverpool at the end of the present month, with the remainder of the cable to connect Kurrachee with Aden. The cable to connect Alexandria with this country is now to be laid through the Islands of Rhodes and Scio to Constantinople, and not by way of Candia, as previously intended. It is expected to be laid in about a month by Messrs. Newall and Co. Captain Fuller, of the *Cyclops*, has fixed on Hallani, one of the Kooris Mooris islands, as a station for the Red Sea telegraph.—A contract has been made with the Gutta Percha Company, on behalf of the Government, for a cable to be laid from Falmouth to Gibraltar, 1,900 miles, which is to be ready in June next. This will be succeeded by one from Gibraltar to Malta and Alexandria, thus giving an independent line, free from Continental difficulties.

We have before us a circular headed "Universal Peace throughout the World," which informs us that "Speedily will be published, with engravings, the particulars of a new peace-inducing system of aggressive warfare, so overwhelmingly destructive in its results, that nations could not exist if brought to bear against them for any protracted length of time, the very knowledge of which (without ever being put to the test), it is believed, when duly appreciated by mankind, must inevitably become the forerunner of peace throughout the world, by making it evident to the meanest capacity, that all standing armies, town and coast fortifications, rifle clubs, vessels of war, and national defences of every kind, would not only be perfectly inefficient, but absolutely powerless to resist, prevent, or lessen in the slightest degree the dreadful consequences of a well-directed attack upon this principle, which in point of cost (as compared with every other system of warfare) would be trivial in the extreme, and of which particulars a brief statement has been already forwarded to the Government, several Members of Parliament, and the Lord Mayor of London." It will only be fair to say that this document proceeds from Mr. W. H. James, C.E., who describes himself as the "(assistant) surveyor of the Liverpool and Manchester and Bolton railroads in the year 1831, and eldest son of the real (but unrequited) originator and founder of the modern railway system." What a happy prospect we have to thank Mr. James for!

NOTICES.

P. S.—It is seldom an easy thing to refer correspondents to situations that will suit them; and in your case we have not, of course, the slightest knowledge of what you are fit for, or of what is fit for you, otherwise we would gladly aid you if we could.

JAMES PARKER, *Camberwell*.—Your letter reached us too late to find a place in this number, but we hope to give it next week.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 1s. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

CORRESPONDENTS' QUERY.

ENDLESS BELTS.

MR. EDITOR.—Will you be so good as to enlighten me on the following?

Suppose (working parallel to each other) two broad endless belts, each two feet diameter, and each stretched over two cylinders or axles, what should be the relative sizes of the cylinders or axles in order to ensure uniform simultaneous motion of the said belts. Your answer will oblige

Yours respectfully,

NOVICE.

September 19, 1859.

[We must commit this and all such inquiries to the attention of correspondents.]

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment:—

STEAM ENGINES, &c., 473.

BOILERS AND THEIR FURNACES, &c., 409.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 424, 448, 460.

SHIPS AND BOATS, including their fittings, 425, 437, 449, 461.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 481.

FOOD AND BEVERAGES, including apparatus for preparing food for man and animals, 451.

PAPER AND PAPER, including machinery for treating fibres, pulp, paper, &c., 407, 437, 463, 465, 466, 468, 470.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 427, 433, 443, 445, 462.

LIGHTING, HEATING, AND VENTILATING, 413, 441, 467.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 416, 421, 422, 460.

METALS, including apparatus for their manufacture, 418, 419, 447.

CHEMISTRY AND PHOTOGRAPHY, 444.

ELECTRICAL APPARATUS, 434, 458.

WARFARE, 464, 471.

LETTER PRESS PRINTING &c., 458.

MISCELLANEOUS, 408, 410, 411, 412, 414, 415, 417, 430, 432, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476.

408. W. E. NEWTON. "Improvements in breech-loading fire-arms." (A communication.) Dated Feb. 12, 1869.

This invention is not described apart from the drawings. *Patent completed.*

409. W. E. NEWTON. "Improvements in sewing machines." (A communication.) Dated Feb. 12, 1869.

This relates, 1, to the manner of drawing the thread through the fabric after the stitch has been completed, and the required tension given to it; and to effect this end the needle used is of the kind known as the double-pointed needle, which is made to pass back and forth through the fabric, and is caught and held at each operation by suitable holding instruments. The loose or free end of the thread is drawn through the fabric by a hook or hooks attached to a travelling endless band. It consists, 2, in alternately gripping and releasing the needle from the needle bars as it passes back and forth through the fabric, carrying with it the thread to form the stitches. It consists, 3, in the arrangement of an adjustable presser foot, to answer the twofold purpose of guiding the needle to the upper needle bar, and to press the thread against the needle to give the necessary tension to the stitch. *Patent abandoned.*

408. J. PARKINSON. "Certain improvements in coffins." Dated Feb. 14, 1869.

This consists in manufacturing coffins or burial cases of earthenware, such as the brown ware made of ordinary clays, or of finer descriptions, such as china clays, or other similar plastic material; or they may be made of ordinary clay, and veneered with clays or cements of finer qualities, and they may be coated both inside and out with a vitreous enamel or glass. *Patent completed.*

409. T. HUNT. "Improvements in steam-boilers or generators, and in the prevention or combustion of smoke." Dated Feb. 14, 1869.

This consists, 1, in the use of transverse flue spaces or chambers having one or more openings made through each, but so arranged that the openings in one chamber are not exactly opposite to those of the next chamber, the whole being placed in the barrel of the boiler of a locomotive engine, or in that portion of a multitubular boiler usually occupied by the tubes and flues. 2. In combining these transverse chambers with tubes, the latter being fixed at the end of the boiler, or flues, or transverse chambers, next the chimney. 3. In arranging the transverse flue spaces in boilers having two or more furnaces or flues, so that one set of transverse chambers may be used in common to all the furnaces, or have a separate series of chambers to each. 4. In constructing the fire-boxes of multitubular or locomotive boilers with a water space or midfeather attached to the tube plate and to the crown plate, such water space projecting a portion

of the distance towards the opposite side of the fire-box, by which the direct current of the gases is diverted from the entrance to the transverse partitions or flues, and thrown towards the fire-door plate through which, or the side plates, atmospheric air is admitted to ensure the prevention of smoke. *Patent completed.*

410. C. SANDERS. "Certain improvements in ornamenting English passe-partouts for photographic pictures, also the glasses used with the same, and which said modes of ornamenting are also applicable to ornamenting photographic frames generally." Dated Feb. 14, 1869.

This consists in applying to photographic mounts the well-known process or processes of gilding, painting, staining, etching, or printing, singly or combined, the inner side of the front glass, around that portion that does not intercept the picture or the moulding that surrounds it. *Patent completed.*

411. J. WRIGHT. "Improvements in reducing and rolling steel and iron wire, and other forms of those metals in long lengths." Dated Feb. 14, 1869.

This consists in winding the wire to be reduced on a cast-iron bobbin or reel, which is then placed on a furnace and heated to the required degree. The wire while heated is passed through rolls and rolled flat, as for watch springs or crinoline steel. There are modifications included. *Patent completed.*

412. J. L. CLARK. "Improvements in the means of working railway signals and switches." Dated Feb. 14, 1869.

In order to work railway signals and switches, the patentee arranges at or near the foot of the signal post, or at or near the switch, two hydraulic cylinders, each furnished with a pipe leading to the place from whence the signal switch is to be actuated, and at this place is a force pump or pumps, by which water may be forced through one or other of the pipes into one or other of the hydraulic cylinders. The pistons or plungers within the cylinders are connected with the signal or switch to be worked in any convenient manner; and they are also connected together so that when the piston or plunger of one of them is forced forward by water being injected into the cylinder the plunger or piston of the other cylinder is pushed back to its original position, and the water which the cylinder contained is caused to flow back by the pipe to the place where the force pump is situated, and there it is caused to flow into a measuring vessel, so that the person working the force pumps may know by the quantity of water returned by the pipe when the required amount has been produced. The employment of the return water to give this indication is the peculiar feature of the arrangement which renders it superior to the systems heretofore proposed for actuating signals and switches at a distance by hydraulic power. *Patent completed.*

413. J. CORCUTT. "Improvements in obtaining light from gases." Dated Feb. 14, 1869.

In obtaining what is called oxy-hydrogen light by directing a jet of ignited gas on to lime or a prepared material, the patentee has found that a better effect is obtained by employing the gases at a far greater pressure than the apparatus now employed will admit of. *Patent completed.*

414. R. CLEGG, F. ANGERSKIN, and J. W. PAGE. "Improvements in making soap." Dated Feb. 14, 1869.

The patentees take one cwt. of the silicate of alumina, and half-cwt. of carbonate of soda in crystals, boil in the water of crystals till on dropping a test quantity on a cool slab it shall appear quite hard; call this A. Then they take one cwt. of the silicate of alumina, 100 cwt. of carbonate of soda, and 10 gallons of water, boil them together for half-an-hour, when they will become amalgamated. Then add of brown resin one cwt., and continue the boiling, when the whole will become a homogeneous mass; then add 56 lbs. of the product of the first process called A, and when sufficiently stiff, pour into moulds, and out into bars. Take of tallow 14 lbs., caustic soda or potash 14 lbs., boil together, adding fresh alkali from time to time, till the soap is perfected; or of this add as much as the quality or character of the soap requires; while hot incorporate, and pour into moulds. *Patent completed.*

415. A. B. CLARK. "Improvements in discharging sewage and water from lands into tidal rivers, and in flooding lands therefrom, also conveying sewage and other waters or liquids across canals and over structures, part of which said improvements being applicable as a substitute for sluice coops and valves." Dated Feb. 14, 1869.

The objects of this invention are effected by means of a hollow vessel in the form of a magnet. The action of this vessel is regulated for draining land by the ebbing and flowing of the tide. In discharging

or conveying water, &c., across canals, &c., the invention consists in constructing a curved hollow channel extending from the part to be discharged to the part to be filled, so that by exhausting such channel of air, the water, &c., will rise thereon, and filling the same will flow through it until the balance of pressure is equal at both extremities. *Patent abandoned.*

416. E. H. ALDRICH. "Improvements in ladies' dress caps." Dated Feb. 15, 1869.

This consists in securing the ordinary materials, such as lace, &c., to the common bobbin net foundation by cement, through the medium of heat and pressure by suitable blocks, and attaching flowers, &c., thereto by metallic ties or fastenings. *Patent abandoned.*

417. C. L. ROBERTS. "The manufacture of an improved cigar." Dated Feb. 15, 1869.

This consists in enclosing within the ends of cigars during manufacture tubes or mouth-pieces of glass, &c., so formed as to admit of one and being readily held within the mouth of the smoker whilst the other is firmly imbedded in the cigar. *Patent abandoned.*

418. R. MUSEY. "Improvements in the manufacture of steel, iron, and cast-steel." Dated Feb. 15, 1869.

This consists in combining cast-iron, decarbonised or partially decarbonised, by passing air through it whilst in the fluid state, with welding cast-steel obtained by melting suitable materials in melting-pots or crucibles heated in ordinary steel melting furnaces, the union of the said welding cast-steel and decarbonised cast-iron being effected by mixing them together whilst both of them are in a melted state, to obtain thereby malleable steel iron or steel suited for commercial purposes. *Patent completed.*

419. F. WALTERS. "The application of the waste heat from puddling furnaces." Dated Feb. 15, 1869.

This invention is not described apart from the drawings. *Patent abandoned.*

420. W. RAYMOND. "An improved life-raft." Dated Feb. 15, 1869.

The inventor employs two semi-cylindrical vessels of corrugated sheet iron, with tapering round ends, the concave portions to be filled in with cork, &c., attached thereto with marine glue, over which he places a complete covering of cork. He then places a covering of canvas, secured by a casing of cork, the whole to be secured by corrugated galvanized iron bands at intervals. There are various other details in connection with the fittings of the raft. *Patent completed.*

421. J. PATERSON. "Improvements in brace buckles and loops, and in braces." Dated Feb. 15, 1869.

This consists in carrying down a piece of metal from the lower bar of the buckle or loop, and in turning up this piece of metal towards the bar so as to form a pipe or tube for the chain or catgut carrying the cords to run in. It also consists in attaching leather tabs to tab chains by eyelets, and a piece of metal attached to each end of the chain. *Patent completed.*

422. J. T. JOYNS. "Improvements in sewing machines." Dated Feb. 15, 1869.

This comprises various improvements in sewing machines, the details of which are too voluminous for us to quote them at sufficient length for an intelligible abstract. *Patent completed.*

423. G. BENDON. "Improvements in joining wire for telegraphic and other purposes." Dated Feb. 15, 1869.

This consists in placing the ends of the wires to be joined within a short tube, which the inventor then strikes with a punch. He prefers to galvanise the joints, or otherwise to apply molten metal, whereby the parts become soldered together. There are various modifications included. *Patent completed.*

424. J. F. TOURRIER. "Preventing oscillation of the last carriage of a railway train, and giving rigidity and steadiness throughout the train." Dated Feb. 16, 1869.

Oscillation is here prevented by placing the action of drawing at the two third back of the carriage, and a secondary or slight action of drawing at the one-third part of the same carriage. The whole is connected by chains or rods with the shackles now in use. The rigidity and steadiness is obtained by coupling chains fitting so as to assist the shackles and supporters to the carriage in case of need. *Patent abandoned.*

425. M. CRAWFORD. "An improved anti-fouling metallic varnish, applicable to ships' bottoms and other similar purposes." Dated Feb. 16, 1869.

The inventor mixes in suitable proportions plumbago or black lead, fine or gum varnish, arsenic, and spirits of turpentine. *Patent abandoned.*

426. S. BAILEY. "Certain apparatus for preventing the ship in mine operations being pulled over the

pulley on which the rope or chain works, to which such skip or cage may be attached, as well as preventing the skip or cage re-descending until put in motion for that purpose." Dated Feb. 16, 1859.

The objects indicated in the title of this invention are effected by certain apparatus, the details of which are too elaborate to be quoted here. *Patent completed.*

437. R. COOKSON and C. W. HOMER. "Improvements in machinery for making bricks, tiles, tubes, and other articles of plastic materials, and in the mode of joining drain pipes." Dated Feb. 16, 1859.

This consists in a combination of machinery by which clay or other plastic material is supplied to a box furnished with a double-acting piston, from which it is forced through dies of the proper shapes for making bricks, tiles, tubes, and other articles. *Patent completed.*

438. C. E. WRIGHT. "Improvements in means or apparatus employed in the nursing or treatment of infants." Dated Feb. 16, 1859.

Here the child is placed in a basket or other receiver, and supported by bands connected to rings and a spring hook. *Patent completed.*

439. R. J. S. PRARCH. "Improvements in weighing and dynamic machines." Dated Feb. 16, 1859.

This relates to the application of a weight on a pendant lever, as the counterbalance to determine the weight of any body, in combination with a lever or series of levers and a circular dial and index-hand, showing the result of the weighing operation. *Patent completed.*

440. P. M. P. BOUFEAUD. "An improved apparatus for supporting the womb." Dated Feb. 16, 1859.

This consists of a mushroom-shaped vessel in esouthebic with an aperture through the centre thereof, and connected to india-rubber or other straps for securing it to the body of the wearer. The vessel is hollow, and may be permanently sealed, or it may be connected with a pipe fitted with tape, and an air-bag for the purpose of inflating and letting out the air from the mushroom-shaped vessel as required. *Patent abandoned.*

441. W. E. NEWTON. "An improved mowing machine or grass harvester." (A communication.) Dated Feb. 16, 1859.

This invention is not described apart from the drawings. *Patent completed.*

442. A. V. NEWTON. "An improvement in the construction of brushes." (A communication.) Dated Feb. 16, 1859.

This consists principally of a method of fitting and fixing the bristles of cylindrical and other like brushes, which method is not described apart from the drawings. *Patent completed.*

443. W. E. NEWTON. "Improved machinery for making bricks." (A communication.) Dated Feb. 16, 1859.

Here a wooden drum is mounted horizontally in bearings, and actuates an endless cloth, which is passed round it and extends down to the ground, and is supported beneath by small rollers so that it may move with facility, and carry forward to the upper or feeding parts of the machinery the clay that is placed thereon. A chain-wheel on the axle of the drum is driven by a chain which passes round a smaller chain wheel on the axle of the feeding or crushing rollers which crush the clay and feed it forward to the pug mill. These rollers are so mounted and arranged that should stones, &c., be found in the clay the rollers will yield, but will be brought back to their original position by springs or counter-weights. The clay is conducted down to a horizontal cylinder, around which are arranged moulds for the bricks, each mould being fitted with a moveable piston. By the rotation of the mould drum, the moulds are brought under the action of a pressor wheel, which forces the clay into the interstices of the moulds. The clay is submitted to a second pressor, while the pistons are also pressed from behind. The bricks are forced out of the moulds by causing the rods at the back of the pistons to be brought against a wheel which will force them outwards, and deliver the bricks on to a plank or board placed on a travelling belt or cloth whereby they are carried out of the machine. *Patent abandoned.*

444. W. H. HORSTMANN. "Telegraphic cables and the mode of constructing the same and laying them down." Dated Feb. 16, 1859.

This invention is not described apart from the drawings. *Patent completed.*

445. J. J. RUSSELL. "Improvements in machinery used for heating and welding the edges of the plates used in the manufacture of cylinders and other articles." Dated Feb. 16, 1859.

Here a standard framing is used from which project two arms. These arms at their outer ends are arranged to receive dies or tools. The upper tool

slides up and down between guides, and is actuated by a cam on a suitable axis, on which there is a cog-wheel driven by a pinion on the main axis of the machine, which is put in motion by a steam engine. There are two fires suitably placed for heating the edges of the plates to be welded. When the overlapping edges are sufficiently heated they are brought between the two dies and pressed between them. *Patent completed.*

446. W. A. O'DONERTY. "An improvement in black-lead pencils and pencil cases." (A communication.) Dated Feb. 16, 1859.

This consists in manufacturing black-lead pencils with the lead running half way through, and india-rubber the other half. Also, in applying a piece of india-rubber to one end of a pencil case. *Patent abandoned.*

447. J. SEGUIN. "Improvements relating to the employment of moving power arising from the tides, and its application to manufacturing, agricultural, and other purposes." Dated Feb. 16, 1859.

This invention is not described apart from the drawings. *Patent completed.*

448. J. S. BRYSON. "A new or improved method of silvering glass." (A communication.) Dated Feb. 16, 1859.

This consists in the use of a solution in water of nitrate of silver and tartrate of ammonia. *Patent abandoned.*

449. J. BREEDEN. "New or improved machinery for the manufacture of taps or stopcocks, and fittings for gas, steam, and water-pipes." Dated Feb. 16, 1859.

This invention is not described apart from the drawings. *Patent completed.*

450. J. EASON. "Improvements in apparatus applicable to tanning, dyeing, and obtaining extracts from vegetable, animal, and mineral substances." Dated Feb. 16, 1859.

This consists of machinery for the tanning of skins, hides, &c., by exhaustion and repletion, caused by hydraulic and hydrostatic pressure. The vessels or tanks the patentee uses for this purpose are composed of iron, wood, or other suitable material, either square or cylindrical, the former in ordinary cases being preferable if of sufficient strength to bear a pressure of from 100 lbs. to 1000 lbs. to the square inch, and are lined with marine glue, gutta percha, lead, copper, or wood as may be required, as the liquor used for tanning in coming into contact with the iron would tend to destroy its tanning properties. *Patent completed.*

451. E. T. COOPER. "Improvements in the use and application of artificial light." Dated Feb. 17, 1859.

The essential condition of this invention is the instantaneous ignition of jets of gas as they issue from a burner, by one or some of them impinging upon and coming in contact with a fixed flame (which may be that of gas or of an oil or other lamp) kept continually burning, in combination with an arrangement whereby the gas is supplied from the main through a branch pipe and turned on to, or cut off from, the burner by the action of an ordinary shut-off cock placed at a distance from it. *Patent abandoned.*

452. G. GRAY. "An improvement in screw wrenches." (A communication.) Dated Feb. 17, 1859.

The short-threaded screw which gears into the bar revolves on a shaft, the end of which shaft is made with a projecting thumb-piece, having a centre pin passing through both, and on one side of the shaft, so that by moving the eccentric shaft round half a revolution the short screw is raised out of gear, thereby allowing the jaws to be opened to their fullest extent without the trouble of the continuous motion of the screw, which is merely pushed into gear for tightening the object to be held. There are other features included. *Patent abandoned.*

453. H. Y. D. SCOTT. "An improvement in the manufacture of cement." Dated Feb. 17, 1859.

In carrying out this invention, which is an improvement upon Scott's patent cement, as patented April 17, 1856, and Feb. 19, 1857, the patentee takes the above-named cement, if it is in lump, which he prefers, and grinds it down in an ordinary cement mill with an equal quantity by measure of chalk, using less or more of that material as desired. *Patent completed.*

454. B. SAILLARD. "An improved mode of obtaining printing-plates from collodion pictures." Dated Feb. 17, 1859.

This relates to the obtaining by the aid of the electrotype process metal printing plates from collodion pictures. *Patent abandoned.*

455. P. E. FRAISSINET. "A new or improved structure of iron, applicable to paving, flooring, bridges, gratings, girders, and other like purposes." Dated Feb. 17, 1859.

This structure is formed of hoop or other iron com-

bined, some of the pieces being flat and others undulated, placed one edge juxtaposed and rivetted at the points of contact. *Patent completed.*

446. T. CARTMILL. "Improvements in treating and purifying gutta-percha." Dated Feb. 17, 1859.

This consists in submitting gutta percha to the action of volatile solvents of two classes, in the proportion of one part by weight to about fifteen parts of solvent. The details are voluminous. *Patent completed.*

447. F. W. EMERSON. "Improvements in the treatment of certain ores of lead, and obtaining from them valuable primary and secondary products." Dated Feb. 17, 1859.

This consists in the treatment of certain ores of lead known as mendipite or oxchloride of lead, phosphate of lead, and the arsenio-chlorides and arsenio-phosphates of lead, native sulphated and carbonates of lead, and all those ores of lead, containing any combination of chlorine, phosphoric acid, arsenous or arsenic acid, carbonic acid, sulphuric acid, or any mixture of the same, so as to produce therefrom oxide of lead for the preparation of its various salts, as the acetate, nitrate, &c., and the various uses for which litharge is now employed, red lead, or minium carbonate of lead, and metallic or pig lead, and from the mendipite or oxchloride of lead a very durable and anticorrosive paint is obtained. *Patent completed.*

448. C. FAY. "Improvements in apparatus for working railway breaks." Dated Feb. 17, 1859.

This invention relates in great part to a former patent dated 18th Dec., 1854, and consists of various peculiar arrangements of mechanism for imparting a rotary motion to the longitudinal break rods of the train, whereby the breaks may be made partly self-acting and self-adjusting, so as to compensate for the wear of the blocks, whilst they are still free to be applied by the hand wheel of the guard when requisite. *Patent completed.*

449. J. H. JOHNSON. "Improvements in apparatus for propelling and steering vessels and other floating craft." (A communication.) Dated Feb. 17, 1859.

This consists in the application and use to and in the propelling or steering of vessels of a scroll-shaped box placed in a horizontal position beneath the surface of the water, and connected to the stern or other convenient part of the vessel. Within this box works a rotary fan or series of vanes attached to a vertical shaft which extends upwards into the vessel, and is driven by a steam engine or other power. A discharge mouth is made on one side of the circumference of the box, and an outlet aperture is made on the upper and under side of the same, both apertures being covered over by a hood or box having a mouth or opening in the contrary direction to the discharge mouth in the circumference of the fan-box or casing. To steer the vessel it is simply necessary to turn the main box round more or less, so as to alter the direction of the jet. *Patent abandoned.*

450. J. J. COLLE. "Improvements in Venetian and other suspended blinds, and in the method of hanging and working them." Dated Feb. 18, 1859.

This consists in having a balance so made and hung as to counterpoise the weight of the blind to which it is attached, and in fixing or hanging the said weight to the lines which pass in the ordinary way over pulleys and through the laths of a Venetian blind, or through the rings, loops, or eyes of a blind of a flexible material. *Patent abandoned.*

451. C. GAETON. "An improved method of treating cane sugar, in order to render it fitter to be employed in brewing, distilling, and wine and vinegar making." Dated Feb. 18, 1859.

This consists in assimilating the properties of cane sugar to those of malt saccharum and fruit sugar prior to its being employed in brewing, distilling, or wine or vinegar making by heating it according to a certain process. *Patent completed.*

452. H. SWAISLAND. "Improvements in box sextants." Dated Feb. 18, 1859.

This consists in the combination of a compass card or needle with an ordinary or other box sextant, so that the bearings as well as the angles of lines may be simultaneously indicated, whilst the advantages of a pocket compass are combined with the sextant. *Patent abandoned.*

453. G. WALLIS. "A new or improved method of engraving, applicable to the production of printing surfaces and the ornamentation of metallic and other surfaces." Dated Feb. 18, 1859.

Here the inventor prepares a drawing upon paper of the design to be produced. The drawing is made with ink or composition containing gum arabic. He applies to the drawing emery powder or sand, which attaches itself to the adhesive ink, &c., and causes all the lines of the design to stand out in relief. He

of drawing between the metal plates, the face of the drawing being the one, and submits the whole to pressure.

IMMERSE. "Improved gearing for mills, applicable for grinding, winnow-purposes requiring motive power. (A communication.) Dated Feb. 18, 1859.

of a central base or pedestal suitably on which is erected a central column pole of which the horse or other animal mill is mounted and moves round on of this column. It carries a wheel orernal teeth, and this wheel gears with in a vertical shaft mounted on bearings a central column; a wheel keyed on to of this shaft gears with a pinion stud in the top of the column. This to or cast of a piece with a bevil wheel on the same stud, which bevil wheel nion whose axis is in direct communica-shaft by which the motive power is to

ARK. "Improvements in emptying in raising other fluid and semi-fluid communication.) Dated Feb. 18, 1859. Inventor projects steam into a metallic h by valves may be perfectly closed; res the air from the capacity, and the a the chamber. When the chamber is valves are shut, and the steam thus enes and produces a vacuum, and the ber being by means of pipes in connec-space from which the muddy matters, drawn, the said matters are thereby er the chamber. *Patent abandoned.*

ARK. "Improvements in pressure communication.) Dated Feb. 18, 1859. movement of a train the dial plate dies which move together as the pre-acted on by the steam, but these two return together to zero if the engineer he maximum pressure which he should iler to be exceeded. The needle which icate the excessive pressure is furnished wheel which rests on a fixed ratchet, s, 1, teeth at one part of its circum-ertain position; 2, a smooth surface umference. The parts are mounted so maximum pressure is arrived at, the gears one tooth, whereby the second ated returning with the first when the am diminishes, which second needle a the dial plate that the regulation n exceeded, and to what extent. The nsists in a new kind of piston for the so in a new application of india- the issue of steam in the manometer.

OWSON. "Improvements in the textile fabrics, and in the machinery loyed therein." (A communication.)

50. the production of a new species of in the weft threads are beaten up the warp, or in undulating lines. certain of the warp threads in the fabrics. *Patent abandoned.*

ter. *Patent completed.*

Improved apparatus for con-

vey trains in motion." Dated

tructed with a lever or levers, a the train is in motion will net as to act on some part of other part of the train, and own or a bell to be rung.

vements in the manufacture, and of angular and other ated Feb. 19, 1859.

s the puddled steel in the ad subjects it to the action

of suitable rolls, whereby the blooms are rolled out into bars of the desired form. In preparing the pile he arranges the metal bars so as to have the fewest practicable number of external joints. There are modifications included. *Patent completed.*

262. W. BASFORD. "Improvements in the method of, and means for, drying bricks and tiles preparatory to their being burnt, and also in the construction of kilns or ovens for burning such bricks, tiles, pipes, pottery, or earthenware, and in the mode of charging or placing these said articles therein to be burnt or fired, and in certain appliances for regulating the heat therein." Dated Feb. 19, 1859.

The specification of this invention is too elaborate to be quoted here at sufficient length for an intelligible abstract. *Patent completed.*

463. S. WHEATCROFT. "Improvements in the method of, and the means for, uniting lace to blond and other fabrics, and also in the apparatus used in manufacturing or converting the same into bonnet and cap fronts, rouches, and such like similar articles of millinery." Dated Feb. 19, 1859.

Here to unite lace and blond the materials are wound on separate reels, and then unwound from these, the blond travelling in one place, the lace in another more elevated. The former in its course passes one of its edges under a little slot guide, and is then carried beneath a piece of sponge fixed in the narrow end of a bent funnel which supplies water to it, so as to moisten and wet the edge of the blond, and dissolve the softening material with which it is dressed. Travelling on from this they then pass under a guide, which has a lateral adjustment for different sizes of fabrics, and into which the lace passes, and is by means of it caused to overlap the adjoining edge of the blond. The two fabrics afterwards come in contact with heated rollers suitably arranged. *Patent completed.*

464. C. F. VASSEROT. "An improved apparatus for manufacturing the strands of wire ropes." (A communication.) Dated Feb. 19, 1859.

This chiefly consists in mounting upon a common axis three rings or wheels of cast-iron, placed parallel and behind each other, the diameters of each regularly decreasing. Upon each of these wheels are mounted a number of bobbins, the number on each being proportionate to the number of strands or wires of which the composing strand is to be made. Upon each bobbin is mounted a wire, and all the wires are wound off the bobbins, and are all drawn and passed through an eye or converging guide, by which they are brought together. The combined mass is then fixed to a hooked rotatory spindle, and the required twist given to it; the bobbins are put in motion by pulleys and wheels. The strands being formed in this manner, a rope is then formed of a certain number of these strands as before. *Patent completed.*

465. C. F. VASSEROT. "An improved carding machine." (A communication.) Dated Feb. 19, 1859.

Here it is proposed to augment the carding surface by adding a third cylinder between the two now employed. This cylinder having a less surface than the large card, has a greater speed. *Patent abandoned.*

466. R. A. BROOMAN. "Improvements in machinery for doubling threads." (A communication.) Dated Feb. 19, 1859.

This apparatus is applicable to all descriptions of doubling machines or frames, whether the bobbins are set in a vertical or a horizontal position. To every bobbin in which the doubled threads are wound, there must be a separate apparatus. Any one of the bobbins in the frame may be stopped without interfering with the rotation of the others. The apparatus consists of three parts, one a pulley or toothed wheel fitted to turn loosely on the bobbin spindle, upon receiving motion from a strap, or from toothed gearing as the case may be; this pulley or wheel is provided with a projecting stud, which, when the parts are all in working order, is caught by a hook in which one end of a curved lever is made to terminate, the opposite extremity of which terminates in a projecting spur; this lever forms the second of the three parts, and is secured to the remaining part by a screw upon which it is free to oscillate. The third and remaining part is a collar terminating in a disc by means of a feather and pressure screw; the collar and disc are fixed on and revolve with the spindle. Each of the threads to be doubled passes through an eye on the outer end of a small lever, and while the threads are whole they keep the outer ends of the lever raised. The inner ends of the levers are turned up, and as long as no thread breaks the turned-up ends of the levers pass free of the projecting spur, and the apparatus, spindle, and bobbin rotate together; but upon the breaking of any one of the threads the inner end of the lever, through the eye of

which the broken thread passed, tilts up and coming in contact with the projecting spur throws the hooked end of the curved lever free from the projecting stud, when the pulley or wheel will cease to carry round the other parts of the apparatus, and will revolve loose on the spindle. *Patent abandoned.*

467. F. P. J. VAN DEN OUWELANT. "Improvements in apparatuses to be applied to fire-places, for obtaining a more complete combustion of the fuel employed therein." Dated Feb. 19, 1859.

This consists in providing the said fire-places with one or more apparatuses through which either steam or air, or both, is caused to pass, and afterwards injected by a sort of screen in the fuel, in order to obtain thereby a better combustion of the gases evolved. *Patent completed.*

468. G. PAUL. "Improvements in spindles and flyers." Dated Feb. 21, 1859.

The mode of fixing the spindle and flyer together, which forms the subject of this invention, is susceptible of various modifications, according to one of which the spindle end is formed with a taper fitting or tapered socket formed in the flyer boss, the flyer being held in its place by a pin fixed in the end of the spindle, and which pin is passed through a groove in the socket of the flyer boss, and then turned round so as to lock it. The outer edge of the flyer boss which bears against the pin is inclined in opposite directions on each side of the groove, so that the turning round of the spindle in the flyer boss in either direction causes the pin to jam or wedge the flyer fast on the spindle. This mode of fixing is thus equally secure in whichever direction the strain upon the flyer may act. *Patent completed.*

469. O. BLAKE. "Improved machinery or apparatus used in the manufacture of glass." Dated Feb. 21, 1859.

The patentee performs the whole of the manufacture of glass from its rough state to its finish, by one set of machinery or apparatus, and on one bed or table. The improved machinery is not described apart from the drawings. *Patent completed.*

470. G. McCULLOCH. "Improvements in machinery or apparatus for spinning, doubling, and throwing silk, and doubling other fibrous materials." Dated Feb. 21, 1859.

The inventor gives motion to the bobbins and spindles at any required difference in order to wind on, and also to obtain the desired twist, by attaching the spindle and bobbin to toothed wheels of different numbers of teeth, which difference is determined by the twist required. The said toothed wheels are put in motion by other toothed wheels having discs of leather resting upon the circumference of plain wheels placed upon a shaft extending from one end of the machine to the other. *Patent abandoned.*

471. T. WILSON. "Improvements in the manufacture and construction of ordnance." Dated Feb. 21, 1859.

This consists in making the barrels of ordnance of hollow cylinders or tubes of annealed cast-iron, the said tubes being of progressively increasing diameter, and fitted upon and connected with one another by the process of shrinking. Also in closing the breech end of ordnance by means of a screw carried by a bow strap or frame jointed to the ordnance, so as to permit the said screw being turned aside or out of the line of the fire when loading the ordnance. *Patent completed.*

472. A. BELFAIRE. "Improvements in the reversing gear of locomotive and other steam engines." Dated Feb. 21, 1859.

Here the reversing lever of the engine has a bearing piece which turns on two pivots or journals, and it has also two ears through which the screw passes, and by which it is held at the bottom of the bearing piece. A piece sliding in grooves in the bearing piece has a screw thread at its lower part, and goes into the screw from which it can also be disconnected according as it is raised or lowered by the catch. When the engine driver wishes to work the lever without the aid of the screw, he presses the catch, and when he wishes to displace the lever by means of the screw, he turns a wheel properly arranged in the required direction. The screw is mounted on a piece moving on pivots so that it can accommodate itself to any inclination corresponding with the position of the lever. *Patent abandoned.*

473. G. HUMPHREY. "Improvements in meters for measuring fluids and gases." Dated Feb. 21, 1859.

This consists of a case containing a circular plate or wheel revolving on an axis, and from which a number of fans or blades project, and travel in a race or course formed by corresponding projections in the case. The passage of the fluid or gas from the inlet to the outlet pipe gives motion to the fans or blades of the wheel, and thence to the ordinary registering dials. *Patent abandoned.*

474. T. SWENSON. "Improvements in the manufacture of alum, and in the mode of, and apparatus for, condensing and destroying gases arising therefrom." Dated Feb. 21, 1859.

This relates to a former patent dated Nov. 27, 1846, and consists of admitting ammonia during the digestion of shale, so that the whole may be conducted in one vessel. The gases evolved are conducted into a condenser of a peculiar arrangement. *Patent completed.*

475. R. JOSEPH. "Improvements in supplying water or other fluids to axle-tree boxes and other journal bearings to lubricate the same." Dated Feb. 21, 1859.

Here a close vessel to contain the lubricating fluid is connected with the axle-tree box by a suitable tube, so that when the fluid lubricator is at the desired level in the box the outlet end of the tube is covered by the fluid. By these means there will be no supply of the lubricating fluid from the close vessel into the box or bearing so long as such outlet from the supply tube is closed or covered by the water, &c., but so soon as the level of the water, &c., in the box or bearing descends below the outlet, and air can pass into the close vessel, the water, &c., will flow into the box or bearing until the outlet of the tube is again covered. *Patent completed.*

476. A. TAPPELL. "Improvements in compositions or compounds used when cleaning glass." Dated Feb. 21, 1859.

Here a decoction is made of Brazil wood, peach wood, and alum, which is mixed with sifted whitening, and also with a composition of soap and chalk. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Sept. 1, 1859.

1993. J. A. SIMPSON. Improvements applicable to hats and other coverings for the head.

1995. T. ARELING. Improvements in locomotive engines.

1997. R. H. COLLYER. Improvements in preparing materials for the manufacture of paper.

Dated Sept. 2, 1859.

1999. J. BERNARD. Improvements in the manufacture or production of boots and shoes, in the machinery, apparatus, and means employed in such manufacture.

2001. W. BROWN, jun., and S. BATHGATE. Improvements in machinery or apparatus for grinding or sharpening the card teeth of carding engines for carding fibrous materials.

2003. W. FEARNS. An improved construction of buoys.

2005. S. D. GOFF, H. DAVIS, S. STRANGMAN, and E. STRANGMAN. An improved method of, and apparatus for, drying malt, corn, and other articles.

2007. E. BUTTON. Improved apparatus for raising sunken vessels.

Dated Sept. 3, 1859.

2011. J. FRISON. Detaching instantly the locomotives from railway carriages, and also for detaching instantly the harness from horses that run away when attached to any carriage.

2013. H. R. L. SCHRAMM. A new process for pressing and separating simultaneously the fibres and pellicles contained in the constituent matters of the beet-root sugar, beer, grains, alcohol, potatoes, beets, and other similar substances.

2015. W. NEILSON. Improvements in steam-hammers.

2017. J. C. NIXON. Improvements in kitchen ranges with combined steamer and hot closets, for cooking, warming, drying, or other purposes.

2019. C. SCHIELE. Improvements in weighing-machines.

2021. B. LAUTH. Improvements in the manufacture of rollers or cylinders for calico printers, and of tubes of copper and brass, or mixtures of those metals.

Dated Sept. 5, 1859.

2023. W. BUSH. Manufacturing granulated acid-leitz powder.

2025. J. W. P. FIELD. Improvements in breech-loading fire-arms.

2027. V. TONELL. Improvements in the manufacture of yeast.

2029. A. V. NEWTON. Improvements in weighing machines. (A communication.)

Dated Sept. 6, 1859.

2031. R. K. GELDARD. Improvements in the method of, and apparatus for making pharmaceutical or other infusions.

2033. F. J. MANCEAUX. Improvements in cartridges.

2035. J. STEWART. Improvements in piano-forte actions.

Dated Sept. 7, 1859.

2037. J. J. LYONS. Improvements in the manufacture of sugar.

2039. G. LAWRENCE. Improvements in the construction of wheeled vehicles.

2041. W. J. J. VARILLAT. An apparatus indicating the level of water in steam caldrons or boilers.

2043. J. P. JOULE. Improvements in apparatus for refrigerating and condensing steam or other vapours, which said improvements are applicable to refrigerating or heating liquids.

2045. A. V. NEWTON. Improvements in the manufacture of ladies' hooped skirts. (A communication.)

2047. E. T. HUGHES. Improvements in machinery or apparatus for forging metals. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2072. M. A. F. MENNONS. An improved arrangement of piston packing, principally applicable to hydraulic apparatus. (A communication.) Dated Sept. 13, 1859.

2073. M. A. F. MENNONS. Improvements in the construction of hydraulic pumps. (A communication.) Dated Sept. 12, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Sept. 20, 1859.)

1138. F. ANGERSTEIN, R. CLEGG, and G. THORRINGTON. Motive power.

1140. J. COMBE. Measuring the hoofs of horses.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 30, 1859.

PATENT LAW REFORM.

ONE of the most unpatriotic things which a man of influence can do in this country is to originate or take part in a needless agitation. The doctrine that our society is based upon a system of compromises is no fiction of the Conservatives, but a manifest and unquestionable fact. It is by the toleration of small evils that we manage to live the peaceable lives that we in Great Britain enjoy. We cannot afford to rush to the Legislature for the suppression of every trivial wrong we see, or the correction of every little abuse which chagrins us. We are content to bear with many evils simply because the attempt to get rid of them would entail greater evils upon us.

Not only, then, do we personally deprecate all that agitation which is carried on for the mere sake of agitation, but we are also averse to every movement that is instituted on insufficient or mistaken grounds. We believe that such movements cause us incalculable harm. They do more to check the progress of useful reforms, and to evoke a spirit adverse to all reform, than any traditional ideas or aristocratic feelings can possibly do. Statesmen who would gladly concede a proper thing, refuse almost everything because things both proper and improper are clamoured for in the same breath—the latter the more loudly of the two. Wisdom cries, but she is not heard, because folly screams so confoundingly; understanding lifts up her voice, but ignorance bawls and drowns it. We really sometimes wonder that the still small voice of reason is ever heeded, or even heard, among us.

With these feelings, we look with anxiety upon the efforts which are from time to time being made by a few individuals in reference to the reform of our Patent Laws. The Patent Law Amendment Act of 1852 was scarcely passed before attempts to get up an agitation for changing it were commenced, and these attempts have been renewed at intervals ever since. A committee has for the last year or two been appointed by a section of the British Association to inquire into and report upon the subject; and the report which that committee recently presented to the Association at Aberdeen will be found on another page of this number. It bears the signatures of W. Fairbairn, E. Sabine, and T. Webster, but, judging from its character, we can hardly believe that any one even of those gentlemen had much to do with its production. It is a clumsily drawn document, at any rate, for in its earliest sentences it tells us that the committee have done nothing decisive in furtherance of their "important objects"—although "those objects" have not been lost sight of—and that the Commissioners of Patents have made no sort of reply to the committee's memorials. These observations can scarcely give the reader any very high opinion of the committee and its labours. A committee that does nothing decisive, and gets no notice taken of what it does do, but merely congratulates itself upon not having gone to sleep and "lost sight of its objects," is neither a very brilliant nor a very useful body, no matter under what auspices it may have organised itself, or whose names it puts to its misgivings. The British Association members, however, seem to rather like that style of thing, for the meeting at which the said report was read, resolved—and resolved unanimously, too—"that the committee on the

"Patent Laws be re-appointed, for the furtherance of the objects set forth in their report."

It would be well if the members of the British Association, when they talk and resolve about the furtherance of "objects," would take some little pains to let us know, precisely and clearly, what those objects are. Unfortunately, however, they have not done so in the present instance. The report contains no definite and succinct statement of the committee's objects, but leaves us to dig them out one by one for ourselves, as best we may. They appear to be: 1, A reduction in the fees paid upon patents; 2, The application of a portion of the patent funds to the purpose of arresting the progress of some patents, with the consent of the applicants; 3, The reward of meritorious inventors who fail to profit by their inventions; 4, The application of the surplus patent funds exclusively to the advancement of science.

Now, some of these objects appear to us to require great consideration. Of course, if we are to set up some narrow class-interest as the only thing to be looked to, it will be easy enough to dispose of them. But such questions as these must be considered with a view to the public interest in general, and not to that of simple inventors, or of patentees, or of patent lawyers, or of patent agents, or of any other class. This, men like Mr. Fairbairn and his colleagues will unhesitatingly admit. Indeed, they seem so much alive to the fact that they scarcely attempt to argue their several points, lest they should put themselves into the position of partisans. We think, with them, that the fees on patents might be reduced with advantage—that, in fact, the seventh year's stamp duty of £100, which is just about beginning to fall due, might be taken off altogether. As to the first of these objects we are therefore agreed. But as to the second, we differ altogether. The proposition appears to us to amount simply to this—that a portion of the patent funds should be absorbed in paying some functionary to do that for inventors which they may be too lazy to do for themselves; or, viewed in another light, it appears to be a plan for making a few more good places under Government for dissatisfied people to get into. At the present moment every man who invents an improvement of any kind can go—thanks to Mr. Woodcroft and the Commissioners—to a Free Library and read for himself the specification of every invention ever before patented in the same branch of manufacture, and thus satisfy himself whether his idea is new or not. And this is all that a paid functionary could do for him. Why, then, should not patents be arrested by the inventors themselves, instead of being arrested by a paid officer with the inventor's consent? As to the committee's third object—if it can be shown how unrewarded but meritorious inventors can be easily and economically recompensed, without opening a door to any attendant abuses, we will cordially second the committee's proposal when it is properly brought forward. But as to their last object—the use of the surplus patent funds exclusively for scientific purposes—we must again differ from them. We have yet to learn why the general revenue of the country should not be contributed to by patentees, many of whom make handsome fortunes out of their patents, and all of whom hope to make a good deal more than they spend upon them.

We have thus glanced at the proposals of the committee in order to show with how little care they are conducting this agitation. The reform of our Patent Laws is a subject deserving more attention than they seem prepared to give it, and we should be glad to see them drop

it altogether if they cannot bring greater zeal and intelligence to bear upon it. We want to see the law reformed in due time; but we fear the committee will hinder rather than hasten useful changes. They are injuring a good cause by loose advocacy, mixing up small and great things, and we call upon them either to resign their work or rouse themselves and set about it heartily.

It is plain that the committee are not so decidedly awake as they suppose. If they have not fallen asleep sufficiently to lose sight of their objects, they have dozed so far as to see some things in a very vague and dreamy manner. They pass over, almost silently, the grave fact that patentees are being sadly bamboozled, not to say cheated, either by the Commissioners, or by the Treasury, or by some official schemer that comes between the two. The committee tell us that one thing the Government propose to do is to build suitable offices for the Commissioners, "including a free library of consultation" for patentees upon an extensive scale. They tell us this, we say, somnolently; but they omit to tell us—indeed, they do not seem even to know—that Mr. Gladstone has put his pen through the proposal, and so rendered the thing impossible, for a year at least. But this is a matter which ought not to be passed lightly over. That library in Southampton Buildings is a disgrace to the country, and the committee might have taken the trouble to find out who it is that has induced its continuance in its present state. We strongly suspect we know the man; and if we can but thoroughly assure ourselves that we do, the mere fact of his holding half-a-dozen offices, and grasping as many salaries, will certainly not save him from the exposure which his ignorance or his superciliousness merits.

THE HOT-BLAST IRON QUESTION.

IN our articles upon the Report of the Admiralty Committee on Marine Engines, published in May last, we stated that Admiral Ramsay, Mr. Nasmyth, and Mr. Ward (who composed the Committee), recommended the entire exclusion of hot-blast iron from all future specifications for new engines, and also mentioned the opposition which the Surveyor of the Navy offered to the recommendation. We have now before us the official report of a speech made a month or two since at the Institution of Mechanical Engineers, Birmingham, by Mr. Neilson, the distinguished inventor of the hot-blast, in which speech we find a trenchant criticism of the Admiralty Committee's proceedings in connection with this matter.

It will be recollected that the experiments upon which the Committee based their recommendation were confined (so far as the Report shows) to a single pig of hot-blast and another of cold-blast iron, these being beaten by sledge hammers, and thrown upon the ground. These experiments, Mr. Neilson asserts, afforded very inadequate data for the judgment of the Committee. They were, he says, a very unsatisfactory mode of ascertaining the relative qualities of hot and cold-blast iron, and not sufficient to afford any ground whatever for so serious a conclusion: "for it was evident that the comparison had been made between a good cold-blast pig and a hot-blast 'cinder pig,' which being made of very inferior materials was far removed in quality from the first class hot-blast pig iron."

It is undoubtedly important, as Mr. Neilson says, that the mistaken views advanced in the Report should be discussed and set right, as the question is one closely affecting the ironmasters, and also the country at large; for if the quality of hot-blast iron is as good as

that of cold-blast, and its cost only half that of the latter, a great waste would be occasioned if cold-blast iron were to be used throughout the machinery for the navy where hot-blast would answer quite as well. "Fortunately, however," the Surveyor of the Navy's replies were "printed throughout with the Report, and were of much value in correcting the erroneous views advanced; and it was there pointed out, in reply to the suggested exclusion of hot-blast iron, that there is no ground for prohibiting its use, simply because it is cheap and may be improperly used; since it is unquestionably productive of benefit when used with judgment." This portion of the Report showed, as Mr. Neilson says, a great ignorance of practical ironmaking, the only difference recognized in the qualities of the two descriptions of iron being that due to the temperature of the blast; and, further, in the experiments witnessed, a single pig of iron only was, as we have said, dealt with in each case, and no mention was made of the locality of production, or the quality of the pig as regarded the material from which it was made.

There are three principal classes of pig iron: namely, cold-blast mine iron, in which the material used is entirely mineral or ironstone from the mine, smelted by cold blast; hot-blast mine iron, made from the same material by hot blast; and hot-blast cinder iron, made from inferior materials, and from the cinder of puddling furnaces mixed in the blast furnace. The quality of each description of iron is due almost exclusively to the materials—that is, the ironstones, fuels, and fluxes used in the furnace for its production, and varies continually even at the same works according to the nature of these materials. The ironstone varies greatly in quality, and there are altogether more than 150 different varieties now known, which are classed into the following eight principal divisions by Mr. Neilson:—

1.—*Black Band* ironstone of Scotland. This is the principal ironstone of Scotland; when smelted with cold blast it produces an inferior iron, and, indeed, as a cold-blast iron can hardly be made, since with the generally inferior fuel there obtained the necessary heat for smelting is with difficulty maintained with cold blast, and the furnaces are consequently liable to serious fluctuations in working: the cold-blast iron of Scotland is scarcely in any instance superior to the hot-blast of that country. When made by hot-blast the iron produced is of a useful quality for foundry purposes, though not very tough.

2.—*Hematite* ironstone of Cumberland; produces either with hot or cold blast a very strong tough pig, forming a good iron either for forge or melting purposes, but red short. It is very good as a toughening mixture.

3.—*Cleveland* ironstone of Yorkshire. This is a different and peculiar quality of ironstone only recently worked, but the iron made from it is now largely exported and also used extensively in this country. With hot blast it produces a serviceable but rather cold-short iron, and a fair quality for castings or forge purposes. The ironstone of this district is invariably smelted by hot blast.

4.—*Clay Band* ironstone of Derbyshire, Staffordshire, and Shropshire; produces a good tough iron with either hot or cold blast, and when judiciously mixed in the furnace a fine quality of pig is obtained for best and general purposes.

5.—*Hydrate* ironstones of the Churnet Valley; these give a very fine soft iron with either hot or cold blast.

6.—*Northamptonshire* ironstone. At first a very inferior description of iron was obtained from this ore; but now with a better management of the furnace specially adapted to this ore, and good fuel, a very soft and fluid quality of melting iron is produced with hot blast, which compares well with the general average.

7.—*South Wales* clay band ironstone; produces fine descriptions of pig iron with either hot or cold blast. The South Wales ironworks are chiefly dependent for their iron making on the excellent quality of fuel obtained there, and the mixtures of ores used

in the furnaces are largely imported from surrounding districts.

8.—*Forest of Dean* ironstone; produces with either hot or cold blast a very fine description of pig iron.

It thus appears that many of the ironstones make a good quality of iron both with hot and cold blast. The largest portion of the iron in the country—more than 90 per cent. of the whole—is now made by hot-blast; in many cases the iron is within a trifling per-centage of the same strength as cold-blast iron. The bad name at first acquired by hot-blast iron arose from not distinguishing between mine and cinder iron, and from the facility afforded by the hot-blast for making iron from very inferior materials, such as flue and tap cinder and the refuse scale of the mills and forges, which could not be worked at all by cold-blast, and of course could produce only an inferior quality of iron. The best class of cold-blast iron is no doubt somewhat superior to the best hot-blast, as a rule; but the difference is not so marked as to warrant any unqualified condemnation of hot-blast, such as is conveyed in the Report referred to, or by any means to justify its exclusion from first-class mechanical purposes, where judiciously used. Hot-blast iron, especially in second runs and for foundry purposes generally, is an excellent material when made from good ores; and the great bulk of best hot-blast castings made from judicious mixtures are quite equal to those of cold-blast iron, and at the same time much cheaper.

Such is the testimony borne by Mr. Neilson, and we think it highly desirable that it should be made as widely known as possible—not, of course, for the sake of iron manufacturers, who understand the facts of the case perfectly well, but in order to prevent engineers and others from being deceived as to the real nature of hot-blast iron.

ENGRAVING BY LIGHT.

WHEN the various photographic processes now in universal use first began to appear, the most unprophetic minds augured that other wonders were in store for us in the same direction. And they were quite right; from that time forward marvel has followed marvel with astonishing rapidity. It is only a week or two since that we inspected the photographs of Raffiello's cartoons at the South Kensington Museum, where complete sets of varying sizes could be purchased at any price between a few pence and a few pounds! This is, of course, but one example of what is now a very common affair—the purchase of splendid photographs almost for a song. But our contemporary, the *Photographic News*—which, as a photographic organ, is unrivalled—last week presented its readers with a fine engraving of the Tuileries, produced by a "photo-glyphic" process which is quite unique, and deserves to be brought prominently before our readers as an illustration of the manner in which the chemical and the mechanical arts are coalescing, as well as for other reasons.

This process has proceeded from Mr. Fox Talbot, to whom we owe the discovery of the method of producing a positive picture from a negative; photography on paper; and the development of the image by gallic acid, beside other discoveries in the art, which have been crowned by this last discovery of photoglyphy. The photoglyphic process is said by our contemporary to be the only one by which a plate can be engraved without being "touched" by the professional engraver. At the present moment there is no other process known by means of which a metal plate can be engraved entirely by chemical action, and with perfect results. On the same authority it is stated that there

can be no sort of question that prints from a photograph on a steel or copper plate are permanent, since they have the same guarantee of permanency as the print of our books, which has already endured in some cases for a very great number of years. Moreover, the extent to which a plate engraved by this process may be made available is almost unlimited. The plate from which the photoglyph given away by our contemporary was printed is of copper. This, after being engraved by Mr. Fox Talbot, was steel-faced. The result of this process is to give us a plate which may be used for printing any number of proofs, on the simple condition of having the steel-facing renewed as soon as the present coating of steel shows signs of wear. The picture represents a portion of the Palace of the Tuileries; and from the richness of the sculpture, the number of the statues, and the numerous fluted columns, is an exceedingly difficult subject to engrave by a chemical process, owing to the great variety of tints it presents. We may therefore point to this photoglyph with confidence as a proof of the great value of Mr. Talbot's process.

Let us now, with the aid of the *Photographic News*, glance at some of the advantages of this process. In the first place, fac-similes of rare engravings or manuscript may be multiplied by it to any extent, with the certainty that these fac-similes are not liable to fade. Again, a most important consideration in estimating the value of this discovery is the extreme comparative cheapness with which, by its means, perfectly stable photographs of paintings or other works of art may be produced. When photographs can be printed with printers' ink with the same facility as from a metal plate engraved in the ordinary manner, without the preliminary cost of engraving, there can be no reason why the most beautiful prints should not be sold at a price but little above the cost of the paper on which they are printed. And not only has this method of engraving a vast advantage over the ordinary process as regards cheapness, but it has the additional and most important advantage of giving a perfectly faithful reproduction of the scene or object without omitting the most minute details. This microscopical minuteness of delineation will render it of great value in the reproduction of anatomical photographs—a matter in which every individual may be interested. The cost of a complete set of photographs of all the various organs, &c., of the human body, taken by the ordinary process, would be so expensive as to place them beyond the reach of most medical men just commencing practice, which is the very time when they most need to keep the knowledge they have acquired fresh in their memory; but when multiplied by this mode of printing, cheapness would be secured without the slightest sacrifice of accuracy or minuteness. Further, in reproducing photographs of maps, either on a large or reduced scale, it is calculated to be of essential service. This branch of photography is practiced now to a considerable extent, but at a cost which would be very materially lessened by employing the photoglyphic process, because for all commercial purposes the reduced or enlarged photograph has to be copied by the engraver on a steel plate, which is rendered unnecessary by the process under consideration. The attention of the Government has therefore been called to this circumstance. There are excellent photographers in the Government service who are perfectly able to test the value and utility of this process, and a small portion of the sum annually expended in photographic manipulations in the different offices, would be sufficient to prove the superior advantages of the photoglyphically-engraved plate over the ordinary

glass negative. "To sum up the advantages of this discovery," says our contemporary, "we may say that it gives the power of producing an unlimited number of photographs of an object at an exceedingly small cost, and of undoubted permanency, whether this object be a painting, a statue, a map, or a rare engraving or manuscript. It has also the additional advantage over the ordinary photographic printing process, that the picture once on the plate the state of the weather afterwards is a matter of no importance."

On another page we publish a detailed description of the manner in which the new art is carried out. But before leaving the question it is necessary to repeat the caution of our contemporary. The action of acids on metals has long been known, and nitric acid has been, and is, extensively employed by engravers in etching on metal plates; but this process must not be confounded with that of Mr. Talbot. In the former case a plate is coated with a substance unassailable by the acid, and the engraver etches his design on this substance, taking care that the etching needle passes through it to the surface of the plate, which is thus laid bare to the action of the nitric acid. It is manifest that, by this method, the degree of perfection of the plate so etched must depend on the excellence of the designer in the first place, and secondly, on his skill in manipulating with the acid. By Mr. Fox Talbot's process the plate is engraved without the intervention of any engraver. He himself, as he admits, has no practical knowledge of the art of engraving, and it may, therefore, be fairly considered that what he has done may be equally well accomplished by any amateur who may possess the perseverance requisite to enable him to succeed. It should be added that Mr. Talbot has wisely obtained a patent for the process, and it cannot therefore be carried out without license from him.

EMPLOYERS AND THE EMPLOYED.

RICHARD COBDEN is a great favourite with the majority of English people. His practical common-sense, his transparent honesty of character and purpose, win for him the esteem even of those who wholly disagree with him in theory; while his name, entwined with Sir Robert Peel's, will go down English history for centuries, as that of the winner of cheap bread for the English people. Mr. Cobden is a born practical administrator; and as such, is a benefactor of his country. But in the region of ideas and primary principles, he, and indeed the whole of the Manchester school of politicians, seems to us to tumble and flounder in an element wholly foreign to them. Only the other day, speaking of the relation between France and England, Mr. Cobden said, that if our armaments to protect us against France cost us six millions a-year (and he believed they cost us nearer twelve), France, as far as we are concerned, had better not be; and that if France, with an eye to England, spent six millions a-year on her armaments, England, for France's sake, had better be at the bottom of the sea. To be sure he did add, "speaking according to political economy;" but one fails to see that this Manchester school ever thinks of men or nations but as buyers or sellers, or believes in any higher economy over them but this shabbiest, prosiest, and meanest, of Profit and Loss.

But this philosophy of life is the only one that has any vitality in the great mass of thinking heads at present. Only look at its dominion in all men say and write about the bond between employers and employed. A clever writer, commenting the other day on the strike of the London builders, surprised us with a

whole series of strange assertions, but which we fear are a wide-spread creed of the present day. They are so well and outspokenly said that we devote an article here to comments on them. We refer to them only as general principles, and not at all as connected with this strike in particular.

"Determined by self-interest," says this writer, "each man has gone to this or that pursuit. Self-interest, pure and simple, pure mere self-advantage is the moving spring of commerce, and is satisfied only by the highest price." Let any bright ingenuous man, occupied in any department of labour, look back to the days of his youth, and ask his own experience if this is true. As far as he can remember, was there not in him a fund of pent-up activity, eager to vent itself upon anything? And did not the calling he selected seem to his youthful wonder almost impossible and miraculous in him who practised it perfectly? Was there not an enchantment in the ingenuity that could build a house or print a page, that fascinated him? Was not enthusiasm the spring that moved him to try to imitate it? And when he first succeeded, was there not a delight that surpassed all the wages in money his work has ever brought him? And was not the "highest price" for his labour sought in after years, more for the sake of his wife and children, or mother or sister dependent on him, than for his own? And has he never been smitten with a sense of the grandeur of the sum total of the achievements of human toil, and felt himself a member of the great commonwealth of labour, carrying on their designs higher and higher through generations? And has he never for a moment forgotten his own self-advantage in the feeling that he was doing his poor stroke of the far-reaching work, whereby all humanity is lodged, clothed, fed, cheered, and adorned? How fine is that saying of Rousseau's, of a task he left untouched in his early manhood: "One thing that hindered me was, myself being in question in the affair; and private interest, whence nothing great or noble ever proceeded, could not draw from my heart the divine soarings which only the most pure love of that which is just and sublime can produce."

We quote again from our text: "The commands of religion and philanthropy are not to be sought in ledgers, any more than the laws of commerce on the walls of churches." This breaking up of human life and duty into separate parts is to dissect and destroy the man. As in his nature man is a unity, as in his person, his senses, thoughts, feelings are interwoven together, so they must be throughout the whole of his practical existence. You might as well try to separate the nervous energy of the body from digestion and the circulation of the blood, as to try to separate a man's "religion" from his "trade." When a man can put away his heart with his morning dressing-gown, and go into his counting-house with only a head and the multiplication table in it, then you may bid him be one person over his ledger and another in his church.

"Strikes," says our writer, "are good; the natural barometers of industry; a means for estimating the fluctuations of labour, superior in accuracy to any other that are possible; only divest them of the unnecessary and perfectly illogical bad temper which generally accompanies them." Most illogical, indeed! Why can't the electric fluids, seeking their disturbed equilibrium, find it again without all their pother of lightning and thunder? Why can't man and wife "strike" work, and be divorced, without bad temper? And why should workmen be ruffled when they fancy themselves wronged, and say, Not another stroke of work

from us till this and that is redressed. We are not apologising for strikes. We believe them more often wrong than right. But we are trying to decipher this doctrine of political economy. And here is its main flaw. It would be quite true and practicable were men mere dead products of nature, mere articles of commerce. To deal successfully with a thing you must first study the nature of the entity you are dealing with. Timber, iron, and cotton you can deal with at your will; though even these have their likes and dislikes, their possibilities and impossibilities, which it is vain for you to neglect. How much more have you to study the temper and ways of your horse in order to manage him! But a man—with all his wants, passions, and imaginings—surely the supply and demand theory has not nicely calculated all the elements, and their intensities, contained in him. We confess that this "exclusion of all passion, sympathy, benevolence from trade" is to us the most diabolical sentiment. How a man communicates himself to his Newfoundland dog; sports with it, shouts to it, makes a companion of it. What a friendship springs up between him and his horse. How he strokes and cheers it, and so admires it, that like Goethe, he often wishes it could speak. But the tradesman and apprentice shall stand behind the same counter all day long for years, and no friendly interest shall spring up, or friendly word be spoken!

The paper we quote from advances still farther in the same direction: "The strikers have really struck their own case to pieces in the very stating of it, for they assign as one prominent reason for what they claim the abundance of unemployed hands. But philanthropy cannot be brought into the question." Here, again, we speak not at all of the London builders and their workmen, but of the general principle—What have the employers to do with unemployed hands? If the supply is greater than the demand, the supply must modestly withdraw and extinguish itself. This is an upheaving of the whole foundation of society, for the men of rank, wealth, power, influence, to say to the labouring population—"We have nothing to do with finding you work. Labour is purely a marketable commodity. If there is too much of it, it must take the lot that an excess of wool or tallow would." On what other condition are some in high places and some in low, but that those who take the high places are to guide and protect those in the lower? Surely the world is wide enough for all the men in it; and human wants are multitudinous enough to appropriate the labour of all that live. The fault is in the overseers, the generals of society, when men and labour cannot find their place. Well was it said of "the multitude" by One we profess to listen to—"They wander as sheep without a shepherd." But our modern friend says: "It is just as rational to demand compassion and benevolence of pure commerce as to pray a falling tile to refrain from hitting an infirm old woman." Happily we are quite sure trade is far from having reached this pitch. We believe there is many a noble master in England who is the friend of his men; who, if it came to that, would say to them, "Rather than pay you wages by which you cannot live, I will pay you more than the market price; and we will both go to ruin together, if better wages are to ruin us."

Whoever has eyes can see that the relation between the employers and the employed is thoroughly deranged amongst us. Everywhere the master complains of his workman, the mistress of her maidservant. The employers complain of insubordination; and those who work

for them have their counter complaints. What is the cause? What the cure? We fear the sound of it is not within the range of the ear of political economy, else we would say, this is only one more sign of the decay of religion amongst us. The essence of religion is reverence: reverence toward every glimpse of God; in your own self, your *me*, first of all; in every phenomenon of nature and of human life; in your fellow-man, "the image of God," and supremely so in those who are your superiors. This is the golden chain that binds each to all, all to each, from the worm of the ground up to the throne of God. Now it is just this decay of reverence for what is below us, and equal to us, and superior to us in God's world, that has snapped the link between the master and his workman. The relation of these two has its foundations in nature; as much so as that of parent and child. And the workman, who has not departed from nature, will instinctively approach his employer with homage. "This man," he will say to himself, "or such as he, is set over me by nature. He has a talent for conceiving and designing, and wealth and opportunity for executing, which I have not. Combined with such as he, we workmen make a world; separated from them we make a chaos. We are born lovers of work, and of work well done apart from any wages it brings. We offer our labour to him who can guide and reward it. Let him be to us a human noble master, and we will swear fealty to him. He, and all his interests, shall be sacred to us. Wherever our eye sees him it shall bless him. We will honour his name at our fireside, and our children shall honour him. Were there need, as our ancestors did for their chiefs, we would fight to the death for him."

And the noble masters, on their side, will care for something more than wages and hours of labour for the men. These millowners and architects will see to it that their men have dwellings fit to live in, and have sufficient there to nourish and cheer. As far as in them lies they will make men of their workmen. They will set up baths for them that they may be healthy and pure. They will give them plots of ground for recreation for themselves and their children. They will set up schools and libraries, places of amusement, places of instruction for them. Free from all condescension and patronage, as men moving amongst men, they will be frank, and courteous, and genial to their workmen, who, without servility, will revere them in return. And what reward is like that which a generous, human, noble master earns for himself? What is so sweet as the trusty, grateful, admiring homage of men? Does purer pleasure ever thrill and quiver through human nerves, than through the sea-captain's, when his sailors doff their caps and hurrah to him? or the farmer's, at the shout of his men at harvest-home? or the millowners, when on a holiday the shout of a thousand workmen greets him?

Shakespeare, who has given us models for imitation of every phase of human nature and life, has a fine sample of loyalty and devotion between servant and master in his drama of *As You Like It*. Our readers no doubt remember it, but will perhaps allow us to remind them of it here.

Old Sir Rowland de Bois is dead; Adam, his old servant, falls to the service of his eldest son, Oliver; Orlando, the younger son, is ill-used by Oliver; Orlando confides his sorrow to the old servant, and not from weakness, for he is the bravest and manliest of men. The old man admires in him the father living in the son's face: "O you memory of old Sir Rowland!" In the quarrel of the two brothers in the open-

ing scene, Adam breaks out—"Sweet masters, be patient; for your father's remembrance, be at accord." Orlando resolving to leave his brother and his home, Oliver bids Adam—"Get you with him, you old dog." Adam: "Is old dog my reward? Most true, I have lost my teeth in your service. God be with my old master! he would not have spoke such a word." Orlando delaying, and urged by Adam to flee, says—"What wouldst thou have me go and beg my food?"

Adam: I have five hundred crowns, "The thrifty hire I sav'd under your father, Which I did store, to be my foster-nurse, When service should in my old limbs lie lame, And unregarded age in corners thrown; Take that: and He that doth the ravens feed, Yea, providently caters for the sparrow, Be comfort to my age! Here is the gold; All this I give you; let me be your servant; I'll do the service of a younger man In all your business and necessities."

Orl.: O good old man; how well in thee appears

"The constant service of the antique world, When service sweat for duty, not for need!"

Dying for food, they reach the Forest of Arden, where a duke lives "in voluntary exile, and a many merry men with him, fleeing the time carelessly as they did in the golden world." Orlando, invited by the duke to sit down at his table, says:—

"Then, but forbear your food a little while, Whiles, like a doe, I go to find my fawn And give it food. There is an old, poor man, Who after me hath many a weary step Limp'd in pure love; till he be first suffic'd, Oppress'd with two weak evils, age and hunger, I will not touch a bit."

Re-enter ORLANDO, with ADAM.

Duke: Welcome: set down your venerable burden, And let him feed.

Good old man, Thou art right welcome as thy master is; Support him by the arm."

Is this romance? Or had Shakespeare seen its like in life? Did he believe that such had been in England's olden times, and that such would be in her coming times—in her mansions, and cotton-mills, and farms?

THE GREAT SHIP'S TRIALS.

BY AN EYE-WITNESS.

(From *Once a Week*.)

THE nominal trial trip of the Great Eastern has yet to take place, but a trip full of trials has already been accomplished by her. Her strength, her speed, her steadiness, her steering capability have all been more or less tested on her passage from Deptford to Portland; and although her baptism was not one of water only, but of blood and of fire, the good ship has doubtless a career of pride and glory before her. Let me here trace, with all care, what I have seen of her perils and her successes, and augur wherein her future hopes and dangers lie.

No one at all accustomed to life on board ship could have embarked on board the Great Eastern on Tuesday, the 6th ult., without observing that her condition was by no means what he might fairly have expected to find. The most careful scrutiny could detect but few signs of organisation, and therefore but few signs of security. The passage from the ladder by which the visitor entered to the saloons in which he hoped to join his fellow-guests, lay through a portion of the ship in which combustible materials, such as shavings and planks, abounded, and in which lighted candles were freely pushed about. This was not an assuring feature in a ship about to

proceed to sea. Another circumstance calculated to impress a careful person unpleasantly was that some, at least, of the "water-tight bulk-heads"—upon the integrity of which the safety of the ship might even on her first journey be made to depend—had passages left through them for convenience in moving from one compartment of the ship to another. But one conclusion could be drawn from this fact, viz., that if the bottom of the great ship should by any fatality become fairly breached in deep water, she would as infallibly go down as if she were hewn out of stone. In addition to these things one looked in vain for a sailorly ship's company. There was certainly a number of riggers on board, and with these there appeared to be mingled a slight admixture of grocers, bakers, and other unprofessional individuals, who had taken upon themselves for the moment, apparently, the functions of mariners. But I must confess their presence inspired me with exceedingly little confidence. Fortunately, however—or was it unfortunately?—there was but little need for sailors, seeing that the ship had not a single sail bent, even to serve a turn upon an emergency! She was furnished, it is true, with two sets of engines, and two propelling apparatuses, so that should any derangement occur to one she would still have another to rely upon. But both engines were new, and both might fail without any miracle; and I should have been better satisfied to have seen that her yards bore canvas. In the captain of the ship I had full reliance; the pilot who was to navigate her was a man of long-tried ability; the immediate control of both the paddle-wheels and the screw was in the hands of the best man for the purpose—Mr. Scott Russell.* In these respects nothing more could be desired. But at the same time it appeared that these gentlemen themselves were in the hands of commercial men by whom their professional desires were over-ridden, or the journey to Portland would not have been undertaken until the ship had attained greater completeness. If this were not so, then Captain Harrison, though he may be a splendid navigator, is an indifferent disciplinarian.

In the passage of the ship to Purfleet on the first day and to the Nore on the next, there was but little that needs remark here. . . . There were, however, a few things which an intelligent eye-witness cannot have omitted to note. The first was the application of steam-power to the rudder. This occurred, in the first instance, before the ship left Deptford. Mr. Lunpley, whose steering-signal apparatus is fitted to the ship—and answers well—desired to have the rudder worked from side to side for a time. This there were not hands enough on the spot to effect. Then it was that Mr. Prowse, the intelligent second officer of the ship, led a rope from the engine of the steam crane to the tiller, and by that means worked the rudder with the utmost ease and facility. This device, noted at the time, was again resorted to off Beachy Head with great advantage, as will hereafter be mentioned. Another notable circumstance was the application of steam-power to the weighing of the anchor. This was resorted to both at Purfleet and the Nore, and without it I see not how the anchor could have been weighed at all by the few seamen on board. A third thing noted was the excessive delivery of cable at the Nore. Twice after the ship was anchored to the satisfaction of the pilot was fathom after fathom of cable allowed to run out, contrary to his instructions, and much to his annoyance. This is mentioned merely as one example of the errors committed, not to say the risks run, from the want of discipline and efficiency of the men on board the ship.

* The proceedings which have taken place at Weymouth, since this article was penned, render it necessary for me to remind the reader that this remark, like another of similar purport which occurs later in the article, implies only that Mr. Scott Russell had the working of the captain's telegraphs to the engine-rooms committed to him, in order that no mistaken instructions might be transmitted to the engine-drivers below. This duty, which was voluntarily undertaken by Mr. Russell, necessarily absorbed the whole of his attention, and was performed to the perfect satisfaction of the pilot and the captain.—E. J. R.

After the weighing of the anchor at the Nore, at seven o'clock on Friday morning, the Great Eastern started, under her own steam, and without the attendance of tugs, on her trip to Portland. From that time until six in the evening the company enjoyed one prolonged display of her great and noble qualities. We had a high wind and a heavily-rolling sea for many hours in succession. All other vessels—and we passed hundreds—either tossed and pitched at anchor with the greatest violence, or ran before the gale under close-reefed sails. But, despite the driving wind and yawning sea of the Channel, our “moving isle” went as steadily forward as if she had still been stealing her silent way down the unruffled waters of the Thames. It was only by the most careful watching that any eye could detect even the slightest motion in her. The ponderous paddle-engines worked as smoothly as the machinery of a lady’s watch, and the screw-engines, although less perfect, require nothing but kindly mention here. Her speed, moreover, was all that could be desired, and more than could have been expected, for, with her engines working at but half-speed, she advanced at more than twelve knots an hour against the beating head-wind. No wonder, then, that every man on board congratulated his fellow on that triumph of human genius over matter in which all were participating.

But at 6-10 P.M., in a moment, in the twinkling of an eye, all congratulations (of that kind) were brought to an end. A report as of a huge but lightly-rammed piece of ordnance—a heavy throb of the deck beneath our feet—the upheaval of the massive foremost funnel—the bursting forth of a thick dense cloud of steam—the descent of a shower of shattered glass and saloon finery—all these, followed by cries and groans never to be forgotten, turned the joy of all into mourning. But the mourning that thus fell in a moment upon the officers, men, and passengers of the Great Eastern at that terrible crisis brought no idle, whining, complaining spirit with it, but a spirit of active aid and beneficence. The rescue of the unfortunate men in the stoke-hole, upon whom a horrible deluge of steam and fire had descended, and the preservation of the ship from the fire that seemed to threaten her, were the first duties to which all applied themselves. Or, if not all, all but here and there a man whom the horror of the scene had overcome. There were a few such, and but a few.

With the “water-tight bulkheads” (so-called) in the state before described, had the bottom of the ship been blown out—or, which is much more probable, had masses of the shattered funnel been “fired” through the bottom (after the fashion of shot from cannon)—nothing but the pumps could have saved the magnificent ship from foundering. Whether the pumps would have been equal to the occasion or not it is impossible to say. The event unquestionably teaches that such a ship should never be sent to sea at all until all that it is proposed to do to make her safe has been done. The precautions against fire—at that portion of the ship, at least—appeared to be ample. On the alarm of fire coming up from below, Captain Harrison and Mr. Scott Russell promptly brought the hoses into play, and the supply of water forced through them by the engines was abundant.

I have already stated that the ship had not a sail bent, and have also remarked that in the event of an emergency Mr. Prowse knew how to steer the ship by steam. Both of these facts assumed importance soon after the explosion. About noon I had discovered that the steering wheel ropes—which were of hemp, and not of hide as they should have been—were being rapidly cut through by the iron sheaves round which they passed. A preventer should have been at once got on, and new ropes rove. Whether these things were done or not, I cannot say. But as we were nearing Beachy Head in the evening, and as a vessel (not seen by me) is said to have been bearing down awkwardly upon us, our wheel-ropes gave way. Strange to say, the paddle-wheel engine was just then either stopped or very greatly reduced in

speed without the directions of Mr. Russell, who had charge of them; and, to complete the troubles of the moment, the screw engines, which had long been a little uneasy, began to groan very audibly. When the ropes went, the ship fell off the wind, turning herself directly upon Beachy Head, and for the first time acquired a very sensible motion. By clapping a rope from the steam crane upon the tiller, command of the helm was speedily attained, and the momentary failures all came to nothing. But they, nevertheless, sufficed to show how very desirable it is that even the Great Eastern should not be taken to sea, as I have said, imperfectly equipped. Had both engines failed on this occasion, as they seemed disposed to fail, or had the inferior wheel-ropes not been supplemented by an extraordinary device, we must either have gone ashore on a lee coast, or trusted to Mr. Trotman’s anchors to keep us off it.

The remainder of the trip to Portland was all that could be desired. Nobly the great ship held on her course down Channel through the succeeding night, over the silver sea, and “under the silver moon.” Nobly she came to anchor next morning within Mr. Cooke’s costly breakwater at Portland. How gladly would we have thronged her high sides, and echoed the cheers of the thousands of welcoming visitors who came to greet us, but for those who below were suffering, and those who had been released from suffering!—but for the destiny which had made our city of the sea a city of the dying and the dead!

The accident which has happened to the Great Eastern in no way interferes with the general question of her ultimate success. For the moment it may depress her interests, but the reaction will inevitably follow, and the ship will be estimated according to her own merits.

The Great Eastern must, however, be fairly dealt with. Let her not be trifled with. Let her water-tight bulkheads be made water-tight; let her yards have sails bent upon them; let her captain have a crew to handle her at his will; let her wheel-lines, and all other parts of her equipment, be of the right material; let her machinery be placed under the care of a sufficiently-large and well-organised staff of engineers; let, in short, the ideas of her designers and builders be faithfully carried out in all respects, and then commercial success will be secured. It will be easy enough for the directors to persuade themselves that many of these things may be deferred, and the ship taken from this place to that, and from that to another, in her present imperfect condition. But public confidence is the indispensable basis of commercial success, and public confidence cannot possibly be gained while the ship is in her present state.

It would not, perhaps, be requiring too much should we ask for the ship now to be delivered up to the captain, and for the directors and their friends to become his guests, and therefore subject to his wishes. The Great Eastern is no longer a mere commercial man’s hobby, or a Londoners’ exhibition; she is a ship, and henceforth must be managed and commanded as a ship should be. Until this is done no good can come of her.

E. J. REED.

REFORM IN THE PATENT LAWS.

In Section G of the British Association at Aberdeen, the following Report of the Committee on the Patent Laws was read:—

At the meeting of the British Association at Leeds for the year 1858, a committee was re-appointed for the purpose of taking such steps as may be necessary to render the Patent System of this country, and the funds derived from inventors, more efficient and available for the reward of meritorious inventors and the advancement of science.

Circumstances beyond control have prevented that committee from taking any decisive steps in furtherance of the important objects entrusted to them; but those objects have not been lost sight of. No reply has been received from the Commissioners of Patents, either to the memorial of the

Glasgow Committee of the British Association, or of the public meeting in Manchester; but some of the questions referred to in those memorials are adverted to in the Report of the Commissioners just issued. From that Report it appears that the number of applications for Patents may be estimated at about 3,000 per annum—that of these 3,000 applications, not more than about two thousand proceed to the final stage of a Patent; and that of the two thousand Patents granted not more than 550 are kept alive beyond three years by the first periodical payment of £50 before the expiration of that term; and the Commissioners anticipate that the fee of £100, payable at the end of the 7th year, will not be paid on more than 100 of the surviving 550 patents. Should this anticipation prove correct, the payment by inventors in fees upon patents not surviving beyond one-half their term of 14 years, will not be less than at the rate of £100,000 per annum, as a direct tax on the inventive genius of the country in addition to, and exclusive of time, labour, and other charges and expenses. The total outlay in respect of those patents may be estimated as at least £250,000, or a quarter of a million per annum. The great work of printing and publishing *in extenso* the Specifications of Patents, granted under the old law—that is, from 1,711 to the 1st October, 1852, in number 12,977—is completed, and the surplus funds hitherto absorbed by this object will be henceforth available for other purposes. That surplus is estimated by the Commissioners at £30,000 for the current year, 1858-9, and to increase in each succeeding year at the rate of £20,000 per annum. This surplus, after providing for the current expenses, is proposed by the Commissioners to be appropriated to the following objects:—

1. The erection of a museum for the preservation and exhibition of models, of which a considerable collection already exists at Kensington.

2. The erection of suitable offices for the Commissioners, including a free library of consultation, upon a more extended scale than already formed by Mr. Woodcroft.

These most desirable and legitimate objects for the application of the “Inventors’ Fee Fund,” cannot, however, be attained without the sanction of the Lords Commissioners of Her Majesty’s Treasury and a vote of Parliament, inasmuch as all the fees levied on inventors are, by a recent change, levied in the shape of stamps, and so pass directly into the Consolidated Fund. These recommendations of the Commissioners will, it is conceived, be regarded as a most legitimate application of the funds of inventors, and as one to which the Parliamentary Committee of the British Association will give their aid, but your committee think that other considerations, and other claims upon the Inventors’ Fee Fund, and upon the annual surplus, whatever its probable amount, should be forthwith urged upon the Commissioners and upon Parliament.

The report of the Patent Committee of the British Association to the Leeds meeting called prominent attention to the two following questions:—

1st. Whether the present scale of payment would be maintained or reduced so as to leave no greater surplus than necessary for official expenses?

2nd. If the present scale of payment be maintained, how shall the surplus be appropriated?

The Commissioners of Patents are in favour of maintaining the present scale of payments, on the ground “that any material reduction in the amount of fees would undoubtedly tend to increase the number of useless and speculative patents, in many cases taken merely for advertising purposes.”

Your committee are not insensible to the force of this observation, but they beg respectfully to doubt whether this money check has any effective operation on the class of cases most requiring to be controlled, and whether the remedy is not worse than the disease in laying an unjustifiable burden on the inventive genius of the country, and

effecting confiscation of property of its own creation.

Your committee are much struck with the fact that the application for about 1,000 patents is not prosecuted to completion, and in many cases probably not beyond the first stage; and that the first periodical payment of £50 at the end of the third year is not made in respect of nearly 1,500 of the 2,000 patents granted; and that the Commissioners anticipated during the ensuing year the surrender or lapsing of no less than 450 out of the 550 patents which survived the first periodical payment.

It must be borne in mind that the granting of patents in this country is practically without control, no attempt having been made to interpose any of the checks urged before the Committee of the House of Lords, in the session of 1851, and provided for in the three Bills of that session, and in the last of the subsequent session, now the law of the land. The payment of £5 on the first application may be regarded as a registration fee; the applicant makes this payment on lodging the papers, obtaining protection and inchoate rights from the moment of his application. This was one of the cardinal features of the new system of 1852. It has been productive of the greatest benefit to invention, especially to those of the poorer class, by enabling them to obtain inchoate rights, and to create property for themselves by a simple record of their inventions without publicity and the obstruction of interested opponents. This power of placing inventions on record is also resorted to in many cases by those who do not wish further to secure or appropriate to themselves property in their ideas and inventions, which forthwith become public property. The 1,500 lapsed patents must be regarded in a different light. These have cost their authors no less than £37,500 for fees and stamps as a direct taxation on their inventive genius, in addition to, and exclusive of, other payments of at least an equal amount. Of these 1,500 patents it is believed that the progress of at least 1,000 might be arrested with the consent of the applicants if the inquiry before the law-officers were substantial instead of merely nominal. Thus a large useless outlay of capital in money and time would be avoided—talents unprofitably employed would be directed into other channels, and the creation of legal rights would be limited and reduced, exactly in proportion as the applications were not proceeded with.

Your committee conceive that the application of a portion of the funds contributed by inventors would be most properly applied to affording them this species of protection against the unprofitable expenditure of time and money; the attempt is surely worth the trial; it would effectually check the prostitution of the patent system to the illegitimate purposes referred to by the Commissioners.

The reward of the meritorious inventor, in cases in which he alone of the public has failed to benefit by the fruits of his genius and the purchase of patent rights in him of extending their terms, was referred to in the Report of the Patent Committee of the British Association at the Leeds meeting, as a legitimate appropriation of a portion of the surplus.

These objects being satisfied, a very large surplus would remain available for the advancement of science, by researches having a direct bearing on the reproductive industry of the country. And if it be thought expedient that more money should be levied on the granting of patents than necessary for the expense of the office, inventors have, it is conceived, an irresistible claim for the expenditure of that surplus upon objects bearing on their interest and the advancement of science.

W. FAIRBAIRN.

EDWARD SABINE.

THOMAS WEBSTER.

Aberdeen, 16th Sept., 1859.

A new yacht, called the "Light of the River," built of steel plates, for Ismail Pacha, of Egypt, by Messrs. George Forrester and Co., of Liverpool, sailed from that port on Wednesday for Alexandria.

THEORY OF NAVAL ARCHITECTURE.

No. IX.

CONTINUING our explanation of the table given on page 299, Vol. I., we observe, that in order to complete the scale of displacement above the load water line, it is assumed that the area of all sections parallel to that of the load water line throughout a depth of one foot is the same as that of the load water section; consequently the solid content of a zone, the base of which is the load water section, and depth one foot, is found, as shown at the bottom of the table to the extreme right, and the weight of an equal volume of sea water. A vertical line ab is then drawn through the point where the scale of displacement meets the load water line, and made equal to one foot on the proper scale for draught of water; a level line bc is drawn through b ; bc is then made equal to the representative of the number of tons of sea-water in the zone, and the points a and c are joined. The line ac is a tangent to the curve at the load water line, and when continued above it, is taken as part of the scale of displacement.

The displacements per inch immersion at all the other water lines have been calculated in the same manner as for the load water line, and are given in the table in their respective columns; tangents to the curve may therefore be drawn at all the water lines, thus forming guides at a number of points for the proper delineation of the scale. We have now explained everything on the table referring to the displacement of our example, and shown how it may be found at any draught of water; it remains for us to describe how the centre of gravity of displacement is found, it being necessary that this point should be situated in the same vertical line as the centre of gravity of the ship, in order to fulfil the fundamental conditions of the equilibrium of a floating body.

To find this point we must show how the centre of gravity of any number of bodies rigidly connected is found. And to commence with the simplest cases with which we have to do in questions relative to Naval Architecture, let us find the centre of gravity of a parallelogram.

Bisect all the sides, and join the points of bisection of the opposite sides, the point in which these lines intersect is the centre of gravity of the parallelogram. This will be readily followed without the aid of a figure.

FIG. 16.

To find the centre of gravity of the triangle ABC , Fig. 16. Bisect the sides AB and BC in D and E respectively, join CD and AE ; the point O in which these lines intersect is the centre of gravity of the triangle. For if we suppose the triangle to be made up of very small slices all parallel to BC , each slice will balance in all positions about AE , since AE would bisect it: consequently the whole triangle would balance in all positions about AE . In the same manner it will be seen that the whole triangle will balance in all positions about CD : it follows, therefore, that O , the point of intersection of AE and DC , is the centre of gravity of the triangle.

To find the centre of gravity of the trapezium $ABCD$, Fig. 17.

Divide the trapezium into the two triangles ABC and ADC by the line AC : find, by the construction above given, the centres of gravity G and H of the triangles ABC and ADC respectively, join GH ; the centre of gravity of the whole trapezium lies in GH . Again, divide the trapezium into the two triangles DAB and DCB by the line DB : find their centres of gravity K and L respectively; join KL , then the centre of gravity of the trapezium is in KL ; but it is also in the

FIG. 17.

line GH , it is therefore in O , the point of intersection of GH and KL .

To come, however, to the general case of finding the centre of gravity of any number of bodies which are rigidly connected, let us first take the case in which the centres of gravity of all the bodies lie in the same plane.

FIG. 18.

Let A_1, A_2, A_3 , &c., ... A_n , Fig. 18, be the respective centres of gravity, situated in the same plane, of the bodies whose weights are P_1, P_2, P_3 , &c., and P_n . Join A_1 and A_2 , and take the point g_1 in it such that $P_1 \times A_1g_1 = P_2 \times g_1A_2$.

Again, join g_1 and A_3 and take g_2 in it such that $(P_1 + P_2) \times g_1g_2 = P_3 \times g_2A_3$.

Then g_1 is the centre of gravity of P_1 and P_2 ; for if g_1 be supported there will be equilibrium in whatever position the bodies are placed: g_2 is also the centre of gravity of P_1, P_2 , and P_3 ; and the same mode of construction can be used until the centre of gravity of all the bodies is found.

Take any point O in the plane through A_1, A_2 , &c., and through it draw the straight lines Ox and Oy at right angles to each other.

Let perpendiculars A_1M_1, A_2M_2, A_3M_3 , &c., g_1M_1, g_2M_2 , &c., be drawn from the bodies, and from g_1, g_2 , &c., upon the line Ox , and let the former be represented respectively by y_1, y_2, y_3 , &c., and let Y represent the perpendicular from the centre of gravity of the system upon the line Ox .

Through A_1 draw A_1RN parallel to Ox , cutting g_1M_1 in R , and A_2M_2 in N ; and Since $P_1 \times A_1g_1 = P_2 \times g_1A_2$ by construction, then by addition

$$P_1 \times A_1g_1 + P_2 \times g_1A_2 = P_2 \times g_1A_2 + P_2 \times Ag_1,$$

$$P_1 \times A_1g_1 = P_2 \times A_1A_2;$$

$$\text{or, } (P_1 + P_2) \times A_1g_1 = P_2 \times A_1A_2;$$

$$\therefore \frac{A_1g_1}{A_1A_2} = \frac{P_2}{P_1 + P_2};$$

Also by similar triangles

$$g_1 R = A_1 N \times \frac{A_1 g_1}{A_1 A_2} = (y_2 - y_1) \cdot \frac{P_1}{P_1 + P_2};$$

or, $(P_1 + P_2) g_1 R = P_2 y_2 - P_1 y_1;$

also, by addition,

$$(P_1 + P_2) (g_1 R + R h_1) = P_2 y_2 - P_1 y_1 + P_1 y_1 + P_2 y_1;$$

or, $(P_1 + P_2) g_1 h_1 = P_1 y_1 + P_2 y_2.$

Similarly,

$$(P_1 + P_2 + P_3) g_2 h_2 = P_1 y_1 + P_2 y_2 + P_3 y_3;$$

&c. = &c.;

and finally,

$$(P_1 + P_2 + P_3 + \&c. \dots + P_n) Y = P_1 y_1 + P_2 y_2 + P_3 y_3 + \&c. \dots + P_n y_n.$$

Therefore, by division,

$$Y = \frac{P_1 y_1 + P_2 y_2 + P_3 y_3 + \&c. \dots + P_n y_n}{P_1 + P_2 + P_3 + \&c. \dots + P_n}.$$

Or, the distance of the common centre of gravity of any system of heavy bodies, whose centres of gravity are situated in one plane, from any line in that plane, is equal to the sum of the products of the weights of the bodies and their respective distances from the same line, divided by the sum of the weights of the bodies.

In like manner it may be shown, if X represent the distance of the centre of gravity of the system from the line Oy , and x_1, x_2, x_3 , &c., the perpendicular distances of A_1, A_2, A_3 , &c., from Oy , that

$$X = \frac{P_1 x_1 + P_2 x_2 + P_3 x_3 + \&c. \dots + P_n x_n}{P_1 + P_2 + P_3 + \&c. \dots + P_n}.$$

When, therefore, Y and X are determined from these two equations, the position of G , the centre of gravity of the system is known.

It may be easily proved that wherever we place the lines Ox, Oy , the position of the centre of gravity G will be found to be invariable, as would, of course, be expected. If the lines be placed so that some of the bodies be on one side of Ox or Oy and the remainder on the other side, then the distances on one side must be considered positive and those on the other side negative, and collecting the products of the weights and distances, those on the latter side must be subtracted from those on the former.

Again, if the lines Ox and Oy pass through one or more of the bodies, as Ox through A_1 and Oy through A_2 ; then the distances y_1 and x_2 vanish, and we have

$$Y = \frac{O + P_2 y_2 + P_3 y_3 + \&c. \dots + P_n y_n}{P_1 + P_2 + P_3 + \&c. \dots + P_n};$$

$$X = \frac{P_1 x_1 + O + P_3 x_3 + P_4 x_4 + \&c. \dots + P_n x_n}{P_1 + P_2 + P_3 + P_4 + \&c. \dots + P_n}.$$

When the centres of gravity of the bodies do not lie in one plane; if three planes be taken at right angles to each other, and perpendiculars x_1, x_2, x_3 , &c. $\dots x_n, y_1, y_2, y_3, y_4$, &c. $\dots y_n$, and z_1, z_2, z_3 , &c. $\dots z_n$, be drawn from the bodies, and X, Y , and Z from the centre of gravity of the whole system upon the three planes respectively, it can be shown by constructions similar to what we have given above that

$$X = \frac{P_1 x_1 + P_2 x_2 + P_3 x_3 + \&c. \dots + P_n x_n}{P_1 + P_2 + P_3 + \&c. \dots + P_n};$$

$$Y = \frac{P_1 y_1 + P_2 y_2 + P_3 y_3 + \&c. \dots + P_n y_n}{P_1 + P_2 + P_3 + \&c. \dots + P_n};$$

$$\text{and } Z = \frac{P_1 z_1 + P_2 z_2 + P_3 z_3 + \&c. \dots + P_n z_n}{P_1 + P_2 + P_3 + \&c. \dots + P_n}.$$

Having obtained the values of X, Y , and Z from the above equations, the position of the centre of gravity of the system is known.

To return, however, to the consideration of the centre of gravity of the displacement of a ship. Since all ships are symmetrical with respect to a vertical longitudinal plane passing through the middle line, it is evident that the point sought must be situated in that plane; we have then at present only to find its position in a fore and aft direction.

For this purpose let us assume that the part of the ship under water is cut up into very thin slices by transverse vertical planes, as represented in Fig. 5, page 56, vol. i., our object now will be

to find the sum of the products of the weights of all these slices, and their respective distances from any transverse vertical plane: since this sum divided by the total displacement will give the distance of the common centre of gravity from the same plane.

Now the weight of any thin slice is equal to the area of its section multiplied by its very small thickness (if we take the weight of an unit of volume as unity), and the product of the weight and its distance from any transverse vertical plane is equal to the area of the section multiplied by its distance from that plane, and again by the very small thickness of the slice.

Take, therefore, a line of abscissæ equal to the entire length of the ship, and having found the areas of all the equidistant transverse vertical sections, already made use of in finding the displacement, multiply them respectively by their distances from the foremost section, for example, and draw ordinates at the several sections, making them equal to the numerical values of the respective products; draw a curve through their extremities, similar to that drawn in dotted lines in the figure above mentioned, and the enclosed curvilinear area will represent the sum of the products of the weights of all the slices and their respective distances from the foremost section; the numerical value of this area divided by the displacement, will give the distance of the centre of buoyancy from the foremost section.

In making the calculations, however, on our table, it is more convenient to divide the distances from the foremost section by the common interval, and after the sum of the products has been obtained, to multiply it by that number.

Referring, therefore, to our table, (page 299) it will be observed that the third column under *Vertical Sections*, contains the quotients of the distances of the transverse sections respectively, from the foremost section divided by the common interval: as $0, \frac{1}{2}, 1, 1\frac{1}{2}, 2$, &c. The numbers in the vertical column headed *Multiples of Areas*, when multiplied respectively by these numbers opposite to them, are inserted to the right in the column headed *Moments*, and represent the relative products of the weights of very thin slices at the several transverse sections, and their distances from the foremost section; their sum, in the present case equal to 11689.05, when multiplied by 12.6, the common interval, and divided by 1832.0, the sum of the column, *Multiples of Areas*, will give the distance, 80.39 feet, of the centre of buoyancy from the foremost section.

It will be seen that the calculations have here been abridged; since to obtain the actual weights, and the products of the weights and their distances from the foremost section, the sums of those two vertical columns should each have been further multiplied by .5, 4.2, and 2; this is, however, unnecessary for our purpose.

We have now completed our description of the calculations on our table, referring to the fundamental conditions of the equilibrium of a floating body; and these must hold whether the vessel swims uprightly of herself, or whether she is merely kept upright by some horizontal forces. Ships, however, must not only be able to stand up of themselves, but must be induced with power to resist inclination when acted upon by external forces: this power of resisting inclination, termed "*moment of stability*," depends, *ceteris paribus*, upon the relative position of the centre of buoyancy, in a vertical direction, and the *Metacentre*.

To find the centre of buoyancy in a vertical direction the same process is gone through as that described for obtaining its position in a fore and aft direction; and the plane from which the distances are measured is that of the load water line. In the table, page 299, let the horizontal column (corresponding to the vertical column headed *Multiples of Areas*) that is, 1.8, 110.4, 103.95, 283.0, 257.1, 838.8, and 236.95, be multiplied by 4, 3, 2, 1, and zero respectively, and the results inserted under them; the sum, amounting to 2765.95, multiplied by 1.5, the common interval

between the horizontal sections, gives for result 4148.925; this quantity divided by 1832.0 will give 2.264 feet for the distance of the centre of buoyancy below the load water section: the rationale of these operations will be readily made out from what has been explained for obtaining the position of the centre of buoyancy in a fore and aft direction. In order to complete our table of calculations we shall give the rule for finding the position of the *Metacentre*, leaving the investigation of it to us: we come to deal with the question of stability in a general way.

Rule to find the height of the *Metacentre* above the centre of buoyancy.

Take the middle line of the load water section as before as the axis of abscissæ, and at the intersections of the several vertical sections let ordinates be drawn, the numerical values of which are the cubes of the respective half breadths of the ship at the load water section; find the curvilinear area thus formed, take two-thirds of the result, and divide by the displacement in cubic feet; the quotient will give the height of the *Metacentre* above the centre of buoyancy.

The calculations given in the last two vertical columns of our table, page 299, headed *Metacentre*, will be readily made out. Thus, the numbers in the first column, headed cubes, are the cubes of the respective semi-ordinates of the load water line; .73 is the cube of .9 nearly; 6.86 of 1.9, &c.; and the second column gives these cubes multiplied by the numbers for finding a curvilinear area; the sum of the latter quantities, or 16703.68, multiplied by 4.2 (one-third the common interval between the vertical sections) gives the curvilinear area 70155.036; two-thirds of this divided by 7691.4, the displacement in cubic feet, gives 6.0781 feet for the height of the *Metacentre* above the centre of buoyancy.

We have now completed the description of our table of calculations, and elaborately shown how the displacement, &c., of a ship may be found when she floats on an even keel, in which case, the extreme horizontal and vertical sections enclose all the displacement except such as may be safely neglected.

Ships are, however, more usually constructed to "sit by the stern," or, to draw more water abaft than forward; in our next article we shall give an example of such a construction; and the student will then be enabled to perform the necessary calculations relating to any design with which he would have to do.

THE COMPASSES OF IRON SHIPS:

BEING A "REPORT ON CHANGES OF DEVIATION OF THE COMPASS ON BOARD OF IRON SHIPS BY 'HEELING,' WITH EXPERIMENTS ON BOARD THE CITY OF BALTIMORE, APIRODITE, SIMLA, AND SLEEVE DONARD," BY MR. JOHN T. TOWSON.*

THE author explained the manner in which the compass committee was first formed, in accordance with the advice of the section he was then addressing, and that two reports had been drawn up, which, with the advice of the Astronomer Royal, had been printed and "presented to both Houses of Parliament by command of Her Majesty." He thanked the Astronomer Royal for his valuable advice and support. There were matters of consideration which the compass committee deemed incomplete; the one was the change which took place in iron ships in proceeding to the opposite hemisphere; the other, the change that was produced by what is technically denominated *heeling*, that is, when the deck of a vessel leaned over through the action of the wind or otherwise; if when looking towards the bow it slanted downwards to the right, it is said to heel starboard, if to the left, to heel port. The first question was undertaken by the late respected Rev. Dr. Scoresby, who proceeded to Australia in the Royal Charter, and whose exertions in the pursuit of this branch of the inquiry shortened a most valuable life. The second question was the sub-

* British Association, Section A., 1859. *Athenæum*.

ject of his (Mr. Towson's) present report. Having described the principles on which his graphic illustration was constructed, he pointed out the unexpected amount of deviation which this source of disturbance (heeling) brought about, amounting in most instances, when the ship's head was in the position to produce the maximum effect, to two or three points in the standard compass, and after to a greater amount as far as the steering compass is concerned. He remarked on several particulars connected with this investigation. Generally the north end of the compass was drawn to the upper side of the ship—the case with seven out of nine compasses on board the City of Baltimore, but in the two steering compasses the needles were drawn in a contrary direction. Mr. Towson explained the theory on which this disturbance arose, partly from subpolar magnetism below the compass, and partly from the disturbance of the inductive magnetism of the ships. In such ships as those under consideration, the following empirical rule held good with respect to compasses favourably placed. When the vertical force as determined either by vibrating experiments or torsion on board the ship maintained the ratio, as compared with the vertical force on shore, in the proportion of nine to fourteen, little or no effect was produced by heeling; and in the case of the Simla this plan of predicting the amount of error was adopted: a moveable upright magnet was applied so as to produce the before-named vertical force, when it was found "with magnet in" no error was produced, although "with magnet out" it amounted to 24° from changing a heel of 10° starboard to 10° port. Another remarkable result appears to exist. He believed that when a ship was built with her head south-east or south-west, little if any effect would be produced by heeling. When examining the magnetic condition of the Sleeve Donard, they were surprised to find that the vertical was very nearly that which would give no effect from heeling. Their talented stipendiary secretary (to whom is due the credit of drawing up the two reports already published) immediately suggested that her head could not have been east when building, which we had taken for granted; and on inquiry we found that on account of her great length she had been built diagonally, with her head south-east nearly. Although Mr. Towson believed that for practical purposes sufficient information had been obtained, yet there were anomalies in their observations that rendered the theories deduced unsatisfactory. This he believed arose from the rapidity with which they were obliged to carry on their experiments, on account of the passing in and out of ships through the docks, from which cause the inductive influence of the earth had not sufficient time to complete its effect. It had been proposed to request the aid of the Admiralty in allowing the Committee to experiment on one of Her Majesty's iron ships in some convenient place for an unlimited time. In conclusion he requested that the Astronomer Royal would favour the Society with his remarks.

The PRESIDENT (the Earl of Rosse) remarked, that he himself had made some observations on the deviation of the compass on board an iron ship which he possessed. After trying magnetic compensation, the magnets were taken away, and a table of errors adopted. He believed that magnetic compensation rendered the compass sluggish.—The ASTRONOMER ROYAL, in reply to the noble President, stated that the magnetic adjustment rendered the directive force exercised on the needle equal, with the ship's head on all points of the compass. Without compensation, with the ship's head on some point, the directive force was frequently neutralized by the ship's magnetic force. He complimented the compass committee for their labours, and the judgment exercised in carrying out their experiments, and he especially referred to the services of Messrs. Rundell and Towson: the former was now carrying out these experiments on board the Great Eastern. He had been prepared to find that the compasses on board iron ships were affected by heeling, but was sur-

prised at the amount, yet convinced of the practicability of compensating this source of error. He considered that the compass committee should not conclude their labours without further experiments, and thought that the Admiralty should place an iron ship at their disposal.—ADMIRAL FITZROY availed himself of this opportunity of bearing his testimony to the value of the services of the Astronomer Royal. Notwithstanding his great exertions in the pursuit of science in various departments, he believed his great work was his labours in connexion with iron ships.—PROFESSOR W. THOMSON wished, so far as his opinion could have any weight, to recommend that the necessity for constant determinations of the error of the compass should be enforced on masters of ships generally, but most strongly on all masters of iron ships. It appeared to him that the only way to use the compass safely is never to trust to it, that is to say, to take azimuths astronomically as often as weather permits, and only to use the compass as a convenience for steering by according to these azimuths, and as a means of keeping as nearly as possible the desired course in the intervals between the azimuthal determinations. When these intervals amount, as they often do, to several days or weeks, no confidence ought to be felt in the dead reckoning within a wide margin of possible error in the course, and the established precautions on approaching those ought to include a large allowance for this uncertainty. No such security can possibly be had for the determination of direction by the compass as the comparison of two or three or more chronometers always gives, in a well-approved ship, for determining absolute time. Professor Thomson referred to the sound and thorough mathematical theory which had been given by Mr. Archibald Smith, and the thoroughly practical manner in which he had applied it, and brought it into form for practical use, in the real circumstance of sea-going ships, by which Professor Thomson believes much has been done to give security to modern navigation. Professor Thomson referred to the case of the wreck of the Tayleur, which the late Dr. Scoresby, whose loss was so much felt by this section, had attributed to a change of the magnetism of the ship (a new iron ship), produced in consequence of being tossed about the Channel in a gale within a few hours after leaving Liverpool; and remarked that it appeared strongly to corroborate the opinion now expressed by the Astronomer Royal, that new iron ships are liable to sudden and great changes of magnetism on being knocked about in rough weather at sea.—Mr. Towson considered that iron ships were as safe as wooden ships, and remarked that they were insured at the same premium as class A 1 at Lloyd's, which would not be the case if they incurred more risk. He believed when the evils of the compass were got over, they would be by far the safer class of ships.

ON THE RAPIDITY OF SIGNALLING THROUGH LONG SUBMARINE TELEGRAPHS:

BEING A PAPER READ BY W. F. JENKINS, AT THE BRITISH ASSOCIATION, SECTION A., 1859.*

THIS paper detailed certain experiments undertaken at the establishment of Messrs. R. S. Newall and Co., Birkenhead, with a view to verify the theory of retardation, and to supply certain constants required. This theory has been well developed by Professor Thomson, and is confirmed by the results of these experiments, which have indeed only been rendered possible by the peculiar construction of Professor Thomson's marine galvanometer. In this instrument momentum and inertia are almost wholly avoided by the use of a needle weighing only 1½ grain, combined with a mirror reflecting a ray of light which indicates deflexions with great accuracy. By these means a gradually increasing or decreasing current is at each instant indicated at its due strength: thus, when this galvanometer is placed as the receiving instrument at the end of a long

submarine cable, the movement of the spot of light, consequent on the completion of a circuit through the battery cable and earth, can be so observed as to furnish a curve representing very accurately the arrival of an electric current. Lines representing successive signals at various speeds can also be obtained, and by means of a metronome dots, dashes, successive A's, &c., can be sent with nearly perfect regularity by an ordinary Morse key, and the corresponding changes in the current at the receiving end of the cable accurately observed. The strength of the battery employed was found to have no influence on the results; curves given by batteries of different strengths could be made to coincide by simply drawing them to scales proportionate to the strengths of the two currents. It was also found that the same curve represented the gradual increase of intensity due to the arrival of a current, and the gradual decrease due to the ceasing of that current. The curves of arrival obtained for lengths of from 1,000 to more than 2,000 nauts were found to agree very closely in general appearance with those given by Professor Thomson's theory (*Proceedings of the Royal Society*, May, 1855). In the curves representing dots and dashes sent at high speeds successive dashes appear in quite a different part of the scale from that occupied by dots. It is in these cases obvious that no delicacy of relay will enable us to indicate both of these signals at a constant adjustment, nor does any increasing strength of battery help us, for though the variations of intensity are absolutely increased, the relative position of such changes to one another on the scale remain unaltered. The magnitude of the first appearance of a current at the far end of a cable may, however, be increased by the use of powerful batteries, and delicate instruments would permit the faintest appearance to be observed. By these means one isolated signal might be sent with great rapidity. Returning to the consideration of successive signals, when the speed of transmission is diminished, the oscillations of the spot increase in size, those for dots and dashes overlap one another, and would give legible Morse signals by means of a relay, the amplitudes of oscillation representing any letter or letters were found to be proportional to the amplitude representing dots. The speed of signalling possible can therefore be measured by that amplitude as soon as in one case it is determined what speed of dot signalling is compatible with the reception of all other combinations of dots, dashes, and spaces. This amplitude is modified by the nature of the receiving instrument, by the nature of the signal, by the skill of the manipulator, &c. The possible speed of signalling was found to be very nearly proportional to the squares of the lengths spoken through; thus, a speed which gave 15 dots per minute in a length of 2,191 nauts, reproduced all the effects given by a speed of 30 dots in a length of 1,500 nauts. At these speeds, with ordinary Morse signals, speaking would be barely possible. In the Red Sea, a speed of from seven to eight words per minute was obtained in a length of 750 nauts. This result agrees very closely with the deduction from the experiments at Birkenhead, and apparently shows that the influence of electro-magnetic induction, due to the disposition of the cable in coils, does not very materially retard the possible speed of signalling. The amplitudes of oscillation representing dots can be thrown into a curve which will be the same for all lengths. By this curve we can determine from one single observation, on any cable, the amplitude of oscillation due to any speed, and, consequently, the possible speed of signalling on that cable. This method, however, of determining the possible speed of signalling, presupposes that a considerable length of the cable shall have been manufactured. Mechanical senders, and attention to the proportion of the various contacts, would materially increase the speed at which signals of any kind could be transmitted. The best trained hand cannot equal the accuracy of mechanism, and the slightest irregularity causes the current to rise or fall quite beyond the limits required for

WHITWORTH'S MEASURING MACHINES.

distinct signals. No important difference was observed between signals sent by alternate reverse currents and those sent by the more usual method. The amplitude of oscillation, and consequent distinctness of signalling, was quite the same in the two cases. An advantage in the first signals sent is, however, obtained by the use of Messrs. Siemens and Halske's submarine key, by which the cable is put to earth immediately on signalling being interrupted, and the wire thus kept at a potential half-way between the potentials of the poles of two counteracting batteries employed, and the first signals become legible, which, with the ordinary key, would be employed in charging the wire. This paper was accompanied by illustrative diagrams, by means of which the results referred to were exhibited to the section.

WHITWORTH'S MEASURING MACHINES.

By Mr. JOSEPH WHITWORTH, the Inventor.*

THE principle of the machine for measuring lengths or thicknesses to the millionth of an inch is simply to compare the end measure of a bar or other piece with a corresponding standard bar of known length, and to ascertain their exact difference of length; the new piece is first made slightly too long, and then gradually brought to the exact length of the standard by successive processes of shortening and remeasurement. The principle is the same as that of measuring by ordinary callipers for end or outside measurement, only that in the latter process the accuracy of measurement is limited by the uncertainty and irregularity in the tightness of fit of the callipers upon each of the two pieces successively gauged by them, causing a variation in the measure obtained on account of the elasticity of the instrument allowing it to yield to a variable extent with the variable pressure of contact. In my machine this pressure of contact between the measuring callipers and the ends of the piece to be gauged is exactly regulated to the same amount in every case, by causing a small parallel steel plate, called

the *gravity piece*, to be held suspended between the two surfaces by this pressure of contact; the surfaces being in each case gradually brought together by a fine micrometer screw, until the fact of the gravity piece becoming suspended between them instead of falling freely marks that the exact limit has been obtained.

The machine is shown in Figs. 1 to 4, one-third full size: it consists of a rigid cast-iron bed *A*, having two heads like lathe heads, fitted with sliding square bars *B* and *C*, each advanced by a screw of 20 threads per inch; the bed has a right-angled *V* groove between the heads, corresponding exactly with the square sliding bars; all the surfaces are made true planes and accurately at right angles. The standard bar for measurement *D* is also square, as shown full size in Fig. 6, fitting exactly in the *V* groove of the bed; and the ends of all the bars are reduced to a circular plane truly at right angles to their axis. In adjusting the machine the bar *B*, shown uncovered in the plan, Fig. 3, is first advanced by means of the divided wheel *F* fixed upon its screw and having 250 divisions on its circumference, each division giving a motion of 1-5000th of an inch; and the final fine-adjustment is then given by moving the bar *C* by means of the second-motion wheel *G*, which has also 250 divisions on its circumference, but carries a tangent-screw *H* driving a wheel of 200 teeth fixed upon the screw of the bar *C*, each division of the wheel *G* consequently giving a traverse of 1-1,000,000th of an inch to the sliding bar *C*. The gravity piece *E* rests at each end upon the projecting edges of the bed, and is moved vertically by the finger between the end of the standard bar *D* and of the sliding bar *C*: it is lifted at one end into the position shown by the dotted lines in Fig. 4, and at first falls freely when released; the sliding bar *C* is then gradually advanced by means of its screw until the pressure of contact is sufficient to support the weight of the gravity piece, which then remains suspended between the ends of the bars when lifted, still moving freely when touched but not being able to fall by its own weight. The exact position of the wheel *G* is then noted, by observing the reading of the divisions on its cir-

cumference: the standard bar *D* is then removed, the bar *C* being drawn back by the wheel *G*. If it be required to produce a duplicate of the standard bar *D*, the proposed duplicate is put into the machine, its ends being made true planes at right angles to its axis; one end of the dupli-

* From the official report of the Proceedings of the Institution of Mechanical Engineers.

cate is placed in contact with the end of the bar *B*, which has remained unmoved since the last measurement; the gravity piece *E* is lifted by the finger and allowed to fall between the other end of the duplicate and the end of the bar *C*. The bar *C* is gradually advanced by means of the wheel *G*, until the fall of the gravity piece is just arrested; the reading of the wheel then indicates whether the proposed duplicate is of exactly the same length as the standard, and shows the difference to the millionth of an inch.

[The machine was exhibited in action by Mr. Whitworth at the close of the meeting of the Institution of Mechanical Engineers, showing that an advance of $\cdot 000001$ inch ($1\text{-}1,000,000\text{th}$ of an inch) was distinctly indicated by the gravity piece becoming suspended instead of falling: and the turning back of the divided wheel through two divisions, representing $\cdot 000002$ inch, was then sufficient to cause the gravity piece to drop, and included consequently all the play in the four bearings of the two screws and two collars. Mr. Whitworth showed also that the fineness of measurement obtained by the machine was sufficient to detect the expansion in length of an inch bar caused by a momentary touch of the finger, the bar then measuring $\cdot 000001$ inch longer than previously; (the expansion of iron being about $1\text{-}150,000\text{th}$ of its length for each degree Fahr., a rise of temperature of $1\text{-}7\text{th}$ of a degree expands an inch bar $1\text{-}1,000,000\text{th}$ of an inch). He stated that in his larger machine for measuring the standard yard, with a bar 36 inches long, the same amount of expansion was shown by the momentary contact of the finger nail. The finest measurement required the precautions of freedom from dust and moisture in the atmosphere, and from any current of air interfering with uniformity of temperature; and the machine was therefore kept in its glass case during the time of use, with an opening only sufficient for moving the micrometer wheel and lifting the gravity piece; by sufficient care in these respects the measure of a space corresponding to half a division on the wheel, or $1\text{-}2,000,000\text{th}$ of an inch, had been rendered distinctly perceptible. Specimens were exhibited of the decimal wire-gauges made by Mr. Peter Stubs, of Warrington, from Mr. Whitworth's standard gauges, having the new decimal Nos. on one side from No. 18 to 300, measuring $\cdot 018$ to $\cdot 300$ inch, and the corresponding old wire-gauge Nos. 26 to 1 on the other side. Also specimens of the Decimal Rules made by Mr. Sampson Aston, of Birmingham, from Mr. Whitworth's standard 30 inch steel bar; 20-inch flat-jointed rules corresponding to the ordinary 2 feet workmen's rules, and 30-inch folding rules ($2\frac{1}{2}$ feet) divided on the four sides. It was stated that the decimal wire-gauges were now regularly supplied by the maker at 7s 6d. each; and the decimal rules at 1s. to 3s. each, several hundreds of the 20-inch rules being already in use.]

In the decimal wire-gauge that I have recommended, I have simply taken the sizes of the old iron wire-gauge, using all those that were accurately represented by thousandths of an inch, and avoiding a change of the sizes now in regular use. All the change I propose is, to call these sizes by a fresh number indicating their exact value in thousandths of an inch. In order to obtain great exactness, the decimal wire-gauges are made from standard flat gauges; the two faces of the gauges are true parallel planes, and I find there is no difficulty in making these standards correct to $1\text{-}40,000\text{th}$ of an inch by means of the measuring machine, from the great accuracy of the sense of touch: a separate gauge is made for each notch in the wire-gauge. The standard gauges for larger dimensions are made in a cylindrical form, from $\cdot 10$ inch up to 6 inches diameter; the smallest size, $\cdot 10$ inch, is shown full size in Fig. 5; these are casehardened and got up very true, and last a long time, as they present a very large extent of wearing surface. I consider that for the shop the use of standard gauges is better than any measuring machine, on account of the difficulty of using a sufficiently delicate instrument

in regular shop work, and the greater liability there would be to alteration in the standards both of diameter and length.

The method of working by end or contract measure is far superior to that of line measure. The latter was the plan previously used, and was adopted for determining the length of the Government standard yard measure, which was a gun-metal bar with two transverse lines upon it 36 inches apart: in order to render minute differences of dimension applicable to the eye, a microscope was fixed over each end of the bar, adjusted by a micrometer screw so as to be exactly over the two transverse lines; the two microscopes were fixed in their position by clamping screws, and the bar being replaced by a second one, the transverse lines on the latter could be compared with the original and the difference measured and registered by the micrometer screw. There was, however, no means of finally correcting the position of the line, but it had to be left when very nearly correct, and the exact amount of error whether in excess or defect then registered by means of the micrometer attached to the microscope. The effect of the microscopes in this case was simply to increase the extent of surface over which the eye traversed in measuring the distance, so as to render minute distances appreciable to the eye; but the extent to which it was found this could be carried by means of microscopes was very limited and uncertain as compared with the method of end measurement. In the measuring machine a motion of $\cdot 000001$ inch ($1\text{-}1,000,000\text{th}$ of an inch) in the screw is represented by nearly $\cdot 01$ inch upon the circumference of the dividing wheel; so that the machine magnifies 40,000 times, and the eye traverses over 40,000 times the space that is being measured. No practical use can be made of microscopes in the workshop; and workmen can only set callipers to a gauge, and require standards of touch or end measure to work to. With practice, the sense of touch is able to detect extremely minute differences of length: by holding a parallel piece, such as one of the wire-gauge standard plugs, between two true-plane surfaces, and making them just touch, I can tell, though blindfold, if one of them is moved $1\text{-}50,000\text{th}$ of an inch nearer to the other, by the difference in the feeling of tightness between the surfaces; and with the measuring machine a motion of one-millionth of an inch is distinctly perceptible.

In reference to engines and machinery of different sizes, I do not think the advantage of exact measurement is less in practice than in the case of a great repetition of the same articles; for whether an engine is of 500 or 20-horse power, an inch and its subdivisions are the same in both, and the same degree of accuracy is required in both, since the best and most satisfactory work is that where the individual parts are accurately made independently by means of gauges, without requiring to be fitted to one another. The best makers of cotton machinery now make the spindles and other working parts by standard gauges alone, and produce the exact fit required in the parts separately, without fitting them to one another before they are finally put together; and the same plan ought, I consider, to be adopted in all engineering and machine shops, as the most economical as well as most perfect mode of executing the work.

Evidence was given by the Astronomer Royal and myself before a select committee of the House of Lords in 1855, with respect to the comparative accuracy of line and end-measure for ensuring a permanent national standard of length. I am desirous that the old standard line-measure should be replaced by an end-measure; for in line-measure the limit of accuracy that could be attained by the use of microscopes was practically only $1\text{-}10,000\text{th}$ of an inch. An objection then urged against the plan of end-measure was that its accuracy depended upon the ends of the bar being truly at right angles to its axis, so as to ensure the same measurement at every point of the ends; but this difficulty is completely met by

the mode I have adopted for their construction, which is simply an adaptation of the principle of the true-plane that formed the basis of all accuracy in mechanical work. The bar, Fig. 6, is laid in a grooved bed consisting of two true-planes, as shown in the diagram, Figs. 7 and 8, with the ends of the bar and of the bed also true-planes, and approximately at right angles to the longitudinal axis; a trial plane is then applied to their ends, as shown by the dotted lines *I*, in Fig. 7, being slightly rubbed to mark the points of contact, and the ends are then reduced to a common true-plane by the ordinary process of scraping. The bar is then turned over, and the same process repeated, taking the correction half off the end of the bar and half off the end of the bed; and by successive repetitions of this process, with the bar resting on each of its four sides alternately, the ends of both the bar and the bed are brought to a true-plane at right angles to the axis of the bar, so that the trial plane is in contact over the entire surface of both, in whatever position the bar is placed. A second objection urged against an end-measure standard was, that it was exposed to alteration from the wear of the ends by use: but the force of this objection disappears when it is considered that duplicate copies of the original standard can be supplied in any quantity, and the original standard itself will be only rarely used for verifying the copies employed for reference. For the original standard, hard jewelled ends are proposed to be employed. I further urged upon the committee at the same time to recognise also a standard inch and foot, and to recommend Government to have standards of these lengths supplied to the manufacturing towns throughout the country. There is actually no authorised legal standard now used except for drapers' measure. A standard inch and foot of end-measure was finally recommended; but the original standard yard of line-measure was still adhered to, and authorised copies of the end-measure standards have as yet been only partially supplied. Correct standards can be truly obtained only by end-measure; and, if Government will determine to carry out the system of end-measure, I am ready to make the country a present of my two measuring machines—the inch machine, and the larger machine, which extends to 40 inches in length. As to the question of Government fixing any universal unit of measure by Act of Parliament, I think it is not at all likely, and would not be the correct course of proceeding; this should be initiated by those using the measure, and I think that if mechanical engineers and manufacturers decimalised the inch and worked to it as the unit of measure, adopting this universally for all their dimensions, they could then urge upon Government for general use that which their experience had proved to be the best.

"PHOTOGLYPHIC" ENGRAVING.

MR. FOX TALBOT'S NEW PROCESS.

A PLATE, either steel, copper, or zinc, having been well cleaned, is to be rubbed with a linen cloth dipped in a mixture of caustic soda and whiting, and afterwards rubbed dry with another clean cloth; this process should be repeated twice. Coat the plate with a solution composed of 1 part of gelatine to 30 parts of water and about 8 parts of a saturated aqueous solution of bichromate of potash. Pour the solution on the plate in the dark room as if it were collodion, drain off the superfluous liquid, and dry over a spirit lamp; the plate is then ready for exposure. Lay the object to be copied upon the plate, and expose in the copying frame in the usual way—from one to several minutes in the sunshine, and for a much longer period, if the sun is obscured; the operator must use his judgment in this matter. When the exposure has been sufficiently prolonged, the frame must be taken again into the dark room, and the plate withdrawn. On removal from the frame it will be seen that a faint image is imprinted on the plate, the light having changed the yellow colour of the gelatine to a brown wherever it has acted. Sprinkle over its sur-

face some very finely-powdered gum copal, and distribute it evenly, care being taken to leave on the plate only a very thin layer. Lay the plate, face upwards, over the flame of a lamp, until the copal is melted: this will require a considerable heat, and its accomplishment will be easily perceived by the change of colour. When this takes place, leave the plate to cool gradually. This process may be termed laying the aquatint ground.

The etching liquid is prepared as follows:—Take hydrochloric acid and add to it as much peroxide of iron as it will dissolve by the aid of heat. When saturated, filter, and afterwards evaporate it, until, as it cools, it solidifies into a brown semi-crystalline mass. This substance is derchloride of iron. It is very greedy of moisture, and absorbs it from the atmosphere, if exposed to it.

Water dissolves a very large quantity of perchloride of iron with the evolution of heat. Saturate a small quantity of water with the perchloride, and pour it into a bottle, which label No. 1. Fill a second bottle with a mixture of five or six parts of this saturated solution, and label it No. 2; and a third bottle with a mixture of equal parts of this solution and water, and label it No. 3.

When the plate is quite cool, pour on it a small quantity of solution from bottle No. 2, and spread it quickly over the plate by means of a camel-hair brush, which has been used for no other purpose. The liquid will speedily begin to act on those parts of the plate on which the light has not acted—it being unable to penetrate through those parts of the gelatinous solution upon which the light has acted. The etching proceeds with considerable rapidity, and should be suffered to continue for some minutes. If the rapidity is too great, it may be checked by adding to No. 2 solution a little of No. 1, doing this with care, as the addition of too large a quantity would render its action too sluggish, and it would require to be stimulated by some of No. 3. When the exact strength required has been thus arrived at, the operator may proceed with confidence in his manipulations. The liquid must be moved about the plate during the whole operation with a camel-hair brush; and when the etching has proceeded far enough, the liquid must be wiped off the plate with a piece of cotton wool, and a stream of cold water poured over it so as to cleanse it as rapidly as possible; then wipe the plate with a clean linen cloth. When faint portions of the picture fail to appear, Mr. Talbot dips a camel-hair pencil in No. 3 solution, and touches these parts, which cause the details to appear with great rapidity; and it is evident that, in the event of its being desirable to check the action of the liquid on any part of the plate this could be accomplished by dipping a pencil in No. 1, and applying it in a similar manner.—*Photographic News.*

THE GREAT EASTERN.

(ABRIDGED FROM THE LETTER OF THE "TIMES" SPECIAL CORRESPONDENT.)

WYMOUTH Sept. 25.

THE repairs necessary for fitting the Great Eastern for sea are daily going forward with the utmost diligence and rapidity. Yet we should be deceiving our readers if we held out the least hope that the Great Eastern will be ready for sea on the 8th of October, or perhaps even during the month of October at all. The fittings of the ship and all matters connected with her sea-going equipment are now entirely in the hands of the Marine department of the Board of Trade. With a passenger ship of such gigantic magnitude, and which when complete will go to sea literally with a population equal to that of many towns, it has been felt that no possible precautions which the greatest experience and most jealous vigilance can suggest should be neglected. In this matter the directors and Captain Harrison are entirely agreed, and have, we believe, asked the Board of Trade to make any suggestions which they think can in any way conduce to the safety and convenience of the vessel. Several suggestions will, therefore, doubtless be offered

at once, and, as a matter of course, complied with to the letter by the executive on board. Some of the most prominent of these suggested improvements are already known, one being that the coal bunkers should all be well ventilated and fitted with pipes through the centre, as is the case with line-of-battle ships, to enable the temperature of the coals to be tested and registered at certain intervals throughout the day. The Great Eastern will always carry the best Welsh coals, which, even when stowed in large quantities, have seldom if ever been known to heat. The Great Eastern, however, will carry no less than 10,000 tons, a quantity which, we need not say, has never yet been put into any vessel, and therefore it has been thought right to guard against even the possibility of accident from this source. Another matter which will probably be altered is the means of feeding the boilers with water. Until the present massive engines were constructed it has always been the rule to make them self-feeding, the auxiliaries being used merely as a stand-by in case of any of the pumps breaking down. The machinery of the Great Eastern was made entirely dependent on its feed water being supplied by the donkey engines—a rather objectionable arrangement, as in case of the donkeys getting out of order, which it has been seen they may do, the machinery must come to a standstill. Feed and bilge pumps will now most likely be fitted to both screw and paddle engines, and the donkeys retained only as a precautionary measure. Two boats, in addition to those already at the davits, will be carried by the Great Eastern when she starts for sea. Each of these, in capacity, will be almost equal to small schooners, as they are to be upwards of 50 feet long, and 13 feet wide, quite capable of taking off at least 100 persons. These with boats of the same description, which have already been made, and those now alongside, will be equal to taking off at least 1,200 crew and passengers. Among the other alterations which will soon be carried into effect is fitting a different kind of stern wheel, and also making a second tiller in the lower deck connected with, though independent of, the upper one. The passage round from the Thames showed that the heat in the stoke holes of one or two of the small auxiliary engines was too much for the firemen. Sliding iron doors will, therefore, be cut in the bulkheads, in order to give them the most complete ventilation. To the auxiliary engines for turning the screw it is intended to attach pumps for pumping water out of the ship or on deck in case of fire. There will thus be two powerful fire engines in the ship, independent of the donkey feeds or feed and bilge pumps, capable in all of throwing upwards of 20 tons of water per minute in case of accident. Another suggested alteration is the removal of the india-rubber packing between the flanges to which the cast iron mast is bolted and filling in with wedges or hornbeam. This will, of course, necessitate the slackening down of the main shrouds, a work both of time and difficulty. Upon minute examination it was found that the forward boilers had not been injured to the extent which was at first imagined, nor yet escaped entirely without damage. The copper plates of these two boilers, upon which the funnel and casing rested, are very much dented in, and many of the iron stays in the interior are either broken or very much bent. Some of the hot-air tubes have also been damaged, but not to a serious extent. The replacing of the stays and such of the tubes as it will be necessary to remove will soon be accomplished, but the restoration of the two damaged boiler-plates must occupy time. A few days will suffice to restore the injured iron supports of the main and lower decks. Thus it is to be hoped that the substantial portions of the ship will be completely refitted in the course of a comparatively few days. But with regard to the erection and equipment of the demolished cabins on the lower deck and in the saloon it would be impossible to speculate on so speedy a completion. Even should the cabins not be touched for six months to come it will not in the least degree prevent

the ship from going to sea, as there is ample berth and cabin accommodation in all the remaining saloons. It is not improbable that in a few days the Great Eastern will leave her present moorings, and go round under easy steam to Southampton Water. Nothing on this point is yet finally decided.

THE GREAT EASTERN EXPLOSION.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—At the close of your last article on "The Great Eastern Explosion" you say—"We should perhaps have satisfied some few readers better if we had said less," &c.

I have been for many years one of your "readers," and I, for one, should have been better satisfied if you had left the question of contract between the company and Mr. Russell to the lawyers. I think very few of your readers feel much interest on this point. There is, however, a question of great interest that has not been, I think, cleared up. You have had an opportunity of inspecting the machinery, and of obtaining such information as should enable you to throw some light upon the matter.

Water-jackets, it may be argued, are perfectly safe; and it may also be argued that a cock in the standpipe is a necessary appliance, to guard against a certain class of accidents; but what can be said of an arrangement whereby the cocks in the standpipe could be closed without the knowledge of the engineers in charge? If the cock was necessary, as Mr. Dixon asserts it was, it should have been entirely under the control of the engineers in charge of the boilers—they should have been made aware of its use—and gearing for working the cock should have been brought to the hand and eye of the man managing the feed. Under such conditions the cock might have been made a tolerably safe appliance, and in case of accident it might have been of use; but to have cocks "boxed up," so that their position even could not be easily seen, was a grand error.

The cock altogether was a simple matter of detail, and its very existence might well have escaped the notice of the man to whose genius we owe the ship; it might even have escaped the notice of the designers of the engines. A man designing a great work does not necessarily, in an engineering point of view, become responsible for minute details; but some one must have been appointed, and must have accepted the responsibility of designing the boiler fittings. This person, whoever he may be, must accept the discredit of having placed a dangerous appliance, connected with the boilers, without providing means for its being worked with safety.

It cannot reflect discredit upon Mr. Brunel, and it need not deteriorate from Mr. Russell's fame as an engineer, but it is entirely beside the question arguing in whose hands the engines were at the time of the accident; the accident was due entirely to the error of fixing a cock in the standpipe without providing the means for bringing the cock under the control of the engineers, and of their control only. Yours, &c.,

A MERTHYR MAN.

Merthyr, 26th Sept., 1859.

[We have to thank our correspondent for the above useful letter, and to say that, while we think him quite correct in arguing that the "contract" had really but very little to do with the cause of the accident, the proceedings of the company's witnesses at Weymouth made it incumbent upon us to deal with the subject as we did. Knowing what we know of the extraordinary circumstances of the case, it would be impossible for us to consider the "lawyers" capable of settling the question satisfactorily. As to the mechanical feature of the case, we quite agree with our correspondent in believing that the employment of an isolated cock in the standpipe, without any indicator for bringing it duly to the attention of the engineer in charge, has proved to be a grave and dangerous error. At the same time we are not sure that even our correspondent would have observed the

gravity and danger so clearly as he now does had it been brought to his knowledge by a less exciting circumstance than an explosion.—*Eds. M. M.*

THE NAVIGATION OF THE AIR.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Public attention is now being directed to this subject, and many persons are in expectation of some great step being made, so as to bring its accomplishment to a mere question of time; and, with the view of helping the subject forward, I submit the following.

I may observe that I have made flying machines of various kinds. The best were those made of paper, with light wooden stays, in the form of Archimedean screws, which were set in motion by winding-up india-rubber bands or springs. They rose in the air while the springs were unwinding.

I made other screws of thin wood, which flew by a smart twist of the fingers. I also made tinued iron screws, with strong spindles, which also rose in the air; but it was requisite to give them a great speed, which was accomplished by means of a string and handle—the operation being similar to spinning a humming-top.

The result of the several experiments convinced me that an immense velocity must be given to any wings or appliances for flying; and, to get that, it would be necessary to have great power in proportion to the weight to be sustained. This was the practical result, and the theoretical one would not be far from it. To obtain a fulcrum from a highly elastic medium it would be necessary to have a large surface acting with great velocity.

The mechanical law seems to present some difficulty, because an increase in speed must have a loss of power in proportion. Notwithstanding this, I am satisfied the thing is to be accomplished without danger, or not more danger than every one encounters on a voyage in a steam-vessel.

The plan I propose is as follows:—A balloon made in the shape of a long cylinder, with pointed ends, capable of sustaining a weight of 400 to 500 lbs.—in fact, rather a small balloon.

The propelling power a steam rocket, or several, made of the best steel plate, capable of sustaining great steam pressure, not less than 1,000 lbs. per inch, or about 1/20th of that from fired gunpowder. The steam discharge from such a rocket would strike the air nearly with the velocity of a cannon ball; and, by its expansion in the form of a cone, several dozens of yards of surface would be acting upon the air, which surface would increase according to the altitude obtained by the balloon on account of the diminished pressure of the air.

The fire could be made from some of the gas from the balloon or from bags of compressed gas.

In place of accidents, several balloons might be used on the principle of several compartments in a vessel all being enclosed in one outside covering, while the balloons themselves might be made of elastic material, so as to prevent any danger from the expansion of the gas, and, at the same time, save the gas that is now let off, and therefore lost, to avoid that danger.

When I first proposed to propel boats by steam rockets acting upon the air, instead of obtaining the fulcrum by the aid of machinery upon the denser medium of water, I was laughed at, and told they would not move. Now, it is admitted that no small steam-boats with machinery will go at half the pace with double the quantity of fuel; and it seems feasible that the same power (acting upon the air) that drives a boat through water against the wind will propel a balloon through air only.

What is wanted towards the carrying of the above plan into successful operation, is a very strong and light steam rocket or boiler; and I trust, both makers' attention to it, as I am frequently applied to for them for propelling boats.

I have used small rockets at an estimated steam pressure of 500 lbs.

I do not propose steam-rockets as a substitute for the steam-engine where a fulcrum is to be had for the motion.

JAMES PARKER.

THE THEORY OF A CENTRAL FIRE.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Numerous experiments on various spots of the globe, and extending to more than 20,000 feet downwards from the level of the sea, have demonstrated that pressure and the density of substances are increasing downwards.

Experiments made on the land appear to have demonstrated that in some shafts in certain localities the temperature rises in proportion as we descend deeper. Now, I must confess that it requires an effort to imagine a point—the centre of the earth—where we are to suppose as existing the maximum of density at the same time with the maximum of heat.

I have met with various springs of the greatest variety of temperature, and have been in mines in Europe, Africa, and America; and, of the former, I found the water of the warm springs always strongly mineralized, carrying mostly sulphur and iron, &c. In mines I found the highest temperature invariably in those that were situated in pyritic ground; for example, at the mine of Tharsis, in Spain (in a deposit of pyrites) you enter, horizontally, through an adit, and traversing several galleries, soon come to a spot where the heat is as intense as in an oven, and that spot is a very few metres below the surface; a similar phenomenon is observed in many other mines.

I quite agree with the remark of your correspondent "T. L. H.," as to the advisability of being always guided by already clearly defined laws of nature in the investigation and search for others; the natural course of our investigation is from the surface downwards. If we were to take for a proved truth the hypothesis of a central fire, our investigation would always be such that every otherwise clearly definable fact would bear the misty veil of hypothesis around it.

I remain, Gentlemen,

Your most obedient servant,

Sept. 25th, 1859.

G. J. G.

Our Weekly Gossip.

THOSE who have watched with care the proceedings of the various sections of the British Association at Aberdeen, will not have failed to notice the active part which Sir John Bowring has played in several of them; and certainly few men of more enlarged mind or judgment could be named among that scientific assemblage. We anticipate, moreover, that when Sir John shall have overcome the serious mental depression which must have ensued upon the domestic bereavement to which he found himself subjected on his return from China, he will devote himself with earnest purpose to the question of that great reform of our coinage—its decimalisation—which is so much needed. We have stated that the Decimal Coinage Association will meet at Bradford on the 10th proximo, and from certain observations of Sir John Bowring, at a meeting of Section II, Economic Science and Statistics, on Tuesday last, there seems little doubt that Sir John intends "breaking a lance" on that subject with Lord Overstone at that place. After a paper had been read on the decimal coinage by Colonel Shortrede, the late Governor of Hong Kong emphatically expressed himself in favour of such a system. The question had been brought up in the House of Commons by himself, and the principle had been adopted by 600,000,000 of the human race. Sir John characterised the "final report," as it was called, of the Decimal Coinage Commission—in which Lord Montague, a member of it, did not concur—as "the most one-sided report ever presented to Parliament," excluding all evidence in favour of the decimal system, and including all possible difficulties in the way of it; a statement which was received with loud applause. We cannot but express satisfaction with these remarks, because they embody our own views, as expressed in former articles on the matter, and demonstrate the fact that Lord Overstone, the parent of that report, is not to have it all his own way. His lordship will find Sir John a doughty antagonist, we think.

What would the Civil Service Commissioners of to-day think of the orthography and composition of the following extract from an Act of Parliament of the reign of King James VI., passed in the year 1597, and relating to a then new coinage of copper for Scotland? "In consequence of great scarcities of small pennies; concludit and resolvit that thair sall

be saine hundred stane wecht of copper unmixed with any other mettale wrought and forged in one mill, and be the said mill maid ready to the prenting, after the accustomed forme of His Majestie's Currier house (Mint), with pyle and currell quhairthrow the same be not counterfite for making of the said exchange and relief of the indigence and miserie of the puir, in penny and twa penny peeces; ilk twa penny pece weyand ane denier twelff granes; quhairof three scoir foure peeces of the saidis twa penny peeces to be in the mark wecht, with twa of the saidis twa penny peeces of remaid of wecht, alsweil havis as licht on the mark wecht thairof; and sax scoir aucht peeces of the saidis penny peeces to be in the mark wecht with foure of the saidis penny peeces of remaid of wecht alsweil havis as licht on the mark wecht of the samin. Having on the one syde the King's face bairhedit with circumscription: *Jacobus 6. D. G. Rex. Sutorum.*, and on the other syde three theissillis distinct, with this circumscription, *Appidum. Edinburgi*, and the saidis peeces to have cours amangis hienes legis for twa pennies and ane penny pece." We commend this indeed to the attention of the C. S. C., whose duty or pleasure it is to infuscate the wits of those who appear before them for examination. The State document of 1597 would thus make an excellent exercise for would-be State servants of 1859. With respect to what is termed "remoid" in the extract above quoted, it may be stated that it refers to the latitude allowed to this day in all mints in producing coins. It is not necessary, for example, that all coins of the same denomination should be of the same weight. In copper coinage this "remoid," or remedy, is considerable even in the British Mint, where great exactitude is observed. We know, for instance, that at present a pound of copper is supposed to be converted into twenty-four pence, but from imperfect working, &c., the exact fractional weight of each individual penny is not preserved. Consequently twenty-four newly-minted pence placed in a scale might be found to weigh rather more or rather less than the 1 lb. The differences plus and minus on a large quantity would, however, fairly balance each other, and just weight would thus be given to the public in gross, if not in detail. A "remoid," or remedy, on the same principle is allowed on coinages of silver or of gold although the individual difference in regard to them is much smaller. The exact remedy allowed to the Mint coiners, or those who contract with the Mint, in the production of pence, halfpence, or farthings, is, we believe, at present 175 grains per pound avoirdupois, the standard weight of the penny being 201.66 grains. With the new mixed metal pieces—when they come—this standard weight and remedy will have of course to be re-adjusted.

The following letter on the Admiralty Works Department comes as a supplement to that which we recently published:—"To the Editors of the *MECHANICS' MAGAZINE*.—Gentlemen,—Your readers need not to travel so far as Pembroke Dockyard to witness the effect of Colonel Green's mania for glass roofs, they can see quite enough of it at the dockyard here. They can see the new saw-mill, with its carpenter's shop over fitted with a glass roof to give light, and a thick canvas awning to keep it dark, the workmen preferring darkness to being baked alive. Near it is a large store for transport clothing, with a glass roof so contrived that the upper floor is like an oven when the sun shines and like a shower bath when it rains—a store, be it remembered, for dry goods. In the victualling yard may be seen a clothing store with another specimen of the fondly-cherished glass roofs. It is said that the women employed therein, during the warm weather, went in a body to the superintendent, and told him that it was impossible to work there and live, when like a kind-hearted man as he is very well known to be (it is to be hoped that he is not the only one in that establishment), he ordered canvas awnings to be fitted forthwith, such as had been previously done in the saw-mill. It is also said that the tailors have asked to be allowed the use of umbrellas during the coming winter; be that as it may, certain it is that six inches of snow is frequently found on the floor of this dry (!!!) store of a winter's morning. Query—were the officers of the yard consulted in the construction of these costly architectural blunders? It is said that the officers and Colonel Green are at this moment at loggerheads about a salt-meat store which is to be built some day or other, Colonel Green maintaining that he as a soldier must know best what is wanted, the officers, (poor simple men) having nothing to prove that they must know best beyond the mere fact of their long experience in the department, an item never attended to as worth any consideration in the all-perfect works department. But surely the Admiralty will not allow another £30,000 to be thrown away in building a

store which the officers protest will not be suitable for the purpose required, either in the construction or the position.—A. STEWART, Mechanics' Institute, Deptford, 24th Sept., 1859.

A correspondent thinks the following letter would add something interesting to our recent notice of the Indian mutiny medal. He says:—"The obverse is the same as on all the previous war medals, the beautiful portrait of Her Majesty, engraved by the late Wm. Wyon, R.A. of Her Majesty's Mint (the reverse designed and engraved by his son). Inscription, 'Victoria Regina.' On the reverse we have Britannia standing resolutely erect looking to her right, helmeted, with a shield bearing the Union crosses on her left arm, and in the hand wreaths. The right arm extended with a wreath for some, we are to suppose, approaching, and as we feel assured, worthy recipient. The figure of Britannia is gracefully characteristic, the attitude, draperies, and expression, calm, resolute, and, if requisite, prepared for renewed action; and seldom has the flowing plume of a helmet overhung a more singularly earnest, yet cheerful and beautiful countenance. By her side, in grim tranquillity, stands a splendidly powerful lion, scrutinising the whole extent of vision in all the stern reality of nature, prepared and competent to destroy whoever may dare to provoke an exertion of that tremendous power, now quiescently passive. Inscription, 'India, 1857-1858. L. C. Wyon.'—R. S."

The following letter, *in re* boat lowering, tells its own tale, and is only another instance of the good that results from an efficient means of quickly and safely lowering boats being on ship-board:—"No. 2179, Royal Mail Steam Packet Company, No. 55 Moorgate-street, London, E.C., 23rd Sept., 1859, to C. Clifford, Esq., London. Sir, in the report upon the log book of the Tasmanian screw steamer belonging to this company, it is stated that on the 81st of July last, while reefing the foretop sail in a strong gale with a heavy sea on, a man fell from the top sail yard overboard, but was picked up again in a short time by one of the cutters fitted with your lowering apparatus. The directors have much pleasure in announcing to you this gratifying result of the use of your invention. Your obedient servant, R. P. T. Reed, Secretary."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment:—

STEAM ENGINES, &c., 513, 533, 534.

BOILERS AND THEIR FURNACES, &c. *None*.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 477, 483, 493, 497, 507, 523, 529, 537.

SHIPS AND BOATS, including their fittings, 480, 502, 515, 544.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 520, 522, 531, 542.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 536.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 481, 482, 483, 486, 487, 489, 494, 495, 499, 503, 509, 510, 514, 517, 519, 525, 528, 532, 538, 545, 546, 550.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 547.

LIGHTING, HEATING, AND VENTILATING, 491, 527, 540.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 504, 516, 548.

METALS, including apparatus for their manufacture, 500, 501, 511, 536.

CHEMISTRY AND PHOTOGRAPHY, 488, 506, 518.

ELECTRICAL APPARATUS, 512.

WARPING, 535.

LITHO PRESS PRINTING &c. *None*.

MISCELLANEOUS, 478, 479, 484, 490, 492, 496, 498, 505, 506, 508, 521, 530, 538, 540, 541, 543, 551.

477. R. W. JOHNSON and W. STABLEFORD. "Improvements in axle-boxes." Dated Feb. 21, 1859.

The object here is to facilitate the application of grease, oil, &c., to the axle-boxes and journals of railway rolling stock, and to protect the lubricating material from dust. The patentees use a syphon or case inserted in the present chamber. On the back part of the axle-box they use a cover or shield with a lubricator, and support the same in position by spiral,

how, or other springs connected to the axle-box. Or they use a double self-adjusting slide with lubricator supported in position from a staple or slide, or from the bottom part of the axle-box, and worked by a lever or levers or with racks and wheels; springs may be used with these slides if necessary. *Patent completed.*

478. J. SCHLOSS. "An improvement in locks or clasps for porte-monnaies, pocket-books, bags, and other like purposes." (A communication.) Dated Feb. 21, 1859.

This relates to a previous patent dated Jan. 16th, 1856, and consists in constructing the bolt which retains the hasp in the lock in the form of a lever having for its fulcrum a pin in the lock plate; one end of the lever secures the hasp while the opposite end is made to terminate outside of and below the case of the lock; a spring inside the case presses the lever into the position to secure the hasp. When the resistance of the spring is overcome by pressing the protruding end of the lever, the hasp is raised out of the lock case either by a spring or by the finger. *Patent completed.*

479. T. SMITH. "Floating wheels for driving machinery." Dated Feb. 22, 1859.

Here the toothed or other wheel is fixed on or to a hollow cylinder which is closed at the bottom, and the driving shaft passes through the nave of the wheel and the bottom of the cylinder. This cylinder is floated in water contained in a reservoir, and motive power applied to such floating cylinder, wheel, and shaft, by gearing or bands for driving the machinery. *Patent abandoned.*

480. W. SORLEYMAN. "Improvements in the construction of propellers." Dated Feb. 23, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

481. J. GRIMOND. "Improvements in the treatment and preparation of jute and other fibrous materials, and in machinery or apparatus employed therein." Dated Feb. 23, 1859.

The patentee softens the jute and other fibrous materials by a heating process. The machinery consists of a heavy block of wood or metal, over which are placed a number of lifting beaters, which are raised by wipers and allowed to fall by their own weight on the jute, &c., as it passes over the block. There are suitable arrangements of bands and rollers for feeding the material to the block to be beaten, and for conveying it from the block after the beating operation. *Patent completed.*

482. J. CURTIS. "The manufacture of military sash net, and machinery to be employed therein." Dated Feb. 23, 1859.

This consists in causing the threads of silk bullion or otherwise to be arranged longitudinally side by side to the required width for forming the sash, and separately attached through the intervention of beads and looped harness to a vertical standard frame, a shifting bar and tappet action being employed for giving an alternating movement to the threads or warp during the elevation and depression of the beads, and consequent opening of the shed, by which arrangement a continuous overlapping of the threads or warp is obtained, and the net or fabric produced, the texture thereof being formed and regulated by the introduction of a wire of the requisite thickness between each shed, and the striking up of the work effected in like manner by hand laths or beaters. *Patent abandoned.*

483. W. S. CLARK. "Improvements in the formation of cast-iron rails for city railways, and also in the method of uniting the ends of two adjacent rails for railway use." (A communication.) Dated Feb. 22, 1859.

This invention cannot be described without reference to the drawings. The applicant claims the construction of an upright self-sustaining rail of cast-iron with car and carriage track combined, and secured and united at the joints by an upright iron splice wedge, and also the application of the splice wedge to any kind of rail, by the addition of cleets and grooves, either in parallel lines to receive and hold the compound wedge, or by conveying lines of cleets at and adjoining the ends of the rail to receive and hold the single wedge. *Patent abandoned.*

484. J. HINE. "An improved book slide." Dated Feb. 23, 1859.

This consists in adding to expansible spring book slides a rack and catch by which the slide when drawn out is retained until released by pressure of the finger on the end of a rod in connection with the catch. *Patent abandoned.*

485. E. LUND. "Certain improvements in the manufacture of fabrics or textures to be used in the construction of umbrellas and parasols." Dated Feb. 22, 1859.

This consists in so weaving the fabric or texture to

be used in covering the frames of umbrellas and parasols that it shall be thicker or more substantial at those parts which by repeated folding are most likely to become worn. *Patent completed.*

486. R. A. BROOMAN. "A method of fixing tannin upon textile fibres, and the employment thereof in dyeing black and dark colours." (A communication.) Dated Feb. 22, 1859.

The patentee claims the method of fixing tannin upon textile fibres by means of chlorides or other salts of tin, or by means of any other equivalent substance, that is, any other substance which will act as a reducing agent and form with the tannin a composition insoluble in water, as described. He also claims the employment of this method of fixing tannin in dyeing black and dark colours. *Patent completed.*

487. T. R. HARDING. "Improvements in the manufacture of card surfaces to be used in preparing fibrous materials." Dated Feb. 23, 1859.

Here the inventor covers the card cylinders with segment cards, the backs or stocks of which are made either of wood or composition and fitted with steel pins; and to ensure the pins being firmly held in the stock he covers the outer face of the segment with sheet metal, which will serve to support the pins; and further to prevent the wood from splitting he covers it with strong canvas. These segments of cards he secures to the cylinder by screws. There are other features included. *Patent abandoned.*

488. W. GOSSAGE. "Improvements in the utilization of alkali-waste." Dated Feb. 23, 1859.

This invention relates to a former one patented, dated Feb. 21, 1857, and comprises the application for the extraction of sulphur from alkali-waste, of carbonic acid gas which is produced during the manufacture of alkali, when sulphate of soda or sulphate of potash is decomposed by means of carbon at a red heat. *Patent completed.*

489. A. W. SMETHURST. "Improvements in machinery for driving looms for weaving." Dated Feb. 23, 1859.

This consists in fixing the driving pulley to a supplementary shaft, to which is fixed a cone; a similar cone is also fixed to the crank shaft, and a strap passes around the cones, thereby communicating motion to the supplementary shaft. The cones are placed in contrary directions. *Patent completed.*

490. S. RIDGE. "Improvements in coupling or making the joints of pipes and other articles." Dated Feb. 23, 1859.

This consists in certain modes of making joints to be placed between the flanges of pipes, &c., requiring to be coupled or jointed together. *Patent completed.*

491. W. ASHTON. "Improvements in gas regulators." Dated Feb. 23, 1859.

This consists, 1, in means of establishing a state of equilibrium in the regulating valve, so that the control of the movements of that valve by the pressure of the gas in the branch may not be interfered with by the irregular pressure of the gas in the street main. 2. In the use of india-rubber in forming the joint or packing by which the back of the regulating valve is insulated. 3. In a like use of india-rubber in making the joint or packing of the hood, disc, or moveable diaphragm of the receiver. *Patent completed.*

492. G. DAVIES. "Improved apparatus applicable to the evaporation of saccharine liquids, and for the concentration of heat for other purposes." (A communication.) Dated Feb. 23, 1859.

This apparatus is applicable principally to the ordinary pans used for boiling sugar, and consists in the application of a floating cover thereto of a peculiar novel construction. *Patent abandoned.*

493. U. SCOTT. "Improvements in carriages, and various parts of the same, which parts may be applied to vehicles of any description." Dated Feb. 23, 1859.

This consists in the application of felt, gutta-percha, india-rubber, &c., in combination with metal in making various parts of carriages. *Patent completed.*

494. W. SHARP. "Certain improvements in machinery for spinning and twisting worsted, cotton, silk, and other fibrous materials." Dated Feb. 23, 1859.

The inventor proposes to prevent the occurrence of "snarls" by the action of pressure upon the threads, which upon some yarns may be continuous, whilst upon others it may be so applied that when the machine is at rest the pressure shall be such that it will gently hold the thread, or operate as a slight drag upon it, thereby preventing it from curling. *Patent abandoned.*

495. S. R. SAMUELS. "Improvements in twist lace machines." Dated Feb. 23, 1859.

Here twist lace machines are constructed so that a larger number of warp bars can be arranged between the ends of the bolts or combs. *Patent completed.*

496. S. RUSSELL. "An improvement in the manufacture of handles for tea and coffee pots, jugs, kettles

knives, daggers, and forks, or any other description of article to which handles are applied." Dated Feb. 23, 1859.

This consists in forming handles of various descriptions of pieces of ivory, cane, bone, horn, or fancy woods, glass, porcelain, or papier mâché, which would otherwise be comparatively useless. *Patent completed.*

407. G. TURNBULL. "Improvements in the permanent way of railways." Dated Feb. 23, 1859.

Here longitudinal sleepers or bearers of iron are used, and the rails are fixed thereto by screw bolts and nuts. The sleepers are formed with a longitudinal groove in them for preventing any lateral movement of the rails. There are other features included. *Patent completed.*

498. H. B. BARLOW. "Improvements in apparatus for condensing steam." (A communication.) Dated Feb. 24, 1859.

This consists in obtaining the requisite vacuum or partial vacuum in the condenser without the aid of a pump, the steam being brought into contact with cold water which is not under atmospheric pressure. *Patent completed.*

499. J. ROBINSON. "Improvements in machinery and apparatus applicable to machines for spinning and doubling." Dated Feb. 24, 1859.

This consists in the application to mules of a vessel containing any lubricating material, and furnished with brushes for cleaning and for distributing the lubricating material. *Patent abandoned.*

500. R. MUSHET. "A new metallic compound or alloy." Dated Feb. 24, 1859.

This consists of a metallic compound or alloy of the metals tungsten, iron, and manganese. *Patent completed.*

501. R. MUSHET. "An improvement in the manufacture of cast steel." Dated Feb. 24, 1859.

This consists in adding to cast steel and combining therewith metallic compound of tungsten, iron, and manganese. *Patent completed.*

502. J. HOLMES. "Improvements in machinery or apparatus for propelling vessels, ships, and boats." Dated Feb. 24, 1859.

Under one modification of the details of this invention a pair of parallel horizontal steam cylinders are fitted up in the stern of the vessel beneath the level of the water-line, one on each side of, and parallel with, the keel. Each piston rod is connected with a horizontally propelling rod, the axes of the two rods being in one and the same line. The vessel receives a powerful propelling motion ahead by the simple reciprocating action of the pair of steam pistons, as when open the floats expose their full propelling surface to the water, and thus secure the necessary resistance for causing the vessel to move. *Patent abandoned.*

503. J. CROSLAND. "Improvements in looms for weaving textile fabrics." Dated Feb. 24, 1859.

This relates to the production of fancy goods, and consists in working two or more shuttle boxes, and regulating the picking motion by the same jacquard machine which forms the shed in the warp. *Patent completed.*

504. A. LANCY, jun. "A new system of watches." Dated Feb. 24, 1859.

This consists principally in a new escapement, which is by simple or dead beat, and its use permits the suppression of the fourth catching—that is to say, one of the four which generally form the movement of a watch. *Patent completed.*

505. J. H. G. D. WAGNER. "Apparatus for cleaning water, and removing all matters in suspension and dissolution contained in it, water intended to feed generators of all sorts (applicable also to other purposes), which besides previous to its getting into the generators is heated to the highest degree without almost any expense." Dated Feb. 24, 1859.

This comprises, 1, the subdivision of the water to be purified into thin continuous sheets or films of indefinite length to be heated in this extended state. 2, The double traverse of the liquid film or sheet over the two surfaces of partitions, upon which are deposited and kept adherent all the incrustations. 3, The heating of the liquid fluid or sheet by the direct contact of steam, and on surfaces directly heated by steam. 4, The condensation of the escaping or waste steam during its continuous flow being increased by means of partition work in the interior of the apparatus, which flow is always inversely to that of the water current, or of any other liquid to be heated. *Patent completed.*

506. J. DALE. "Improvements in concentrating caustic alkalies, and in applying a product therefrom to the purpose of obtaining motive power, and to other purposes." Dated Feb. 24, 1859.

This consists in a method of economizing the evaporation of solutions of caustic alkalies. This is accomplished by placing the fluid in a close vessel, to

which heat is applied by any ordinary means, and the steam arising therefrom is applied as a heating medium for evaporating another quantity of solution, to effect which the said steam may be caused to pass into a coil of piping, into a false bottom, or other ordinary evaporating apparatus. *Patent completed.*

507. E. PRICE and E. HAWKINS. "Improvements in the mode of forming fish plates, and in the method of fixing or attaching them to the joints of rails on railways." Dated Feb. 24, 1859.

This invention is not described apart from the drawings. *Patent completed.*

508. A. C. KEILY. "Improvements in apparatus for drawing-off fluids." Dated Feb. 24, 1859.

This invention consists in connecting a vent-hole with a tap by an elastic tube, so that when the tap is turned the vent is opened, and vice versa. *Patent abandoned.*

509. A. REID and R. TONGE. "Certain improvements in weaving, and in the machinery employed therein." Dated Feb. 25, 1859.

This invention is not described apart from the drawings. *Patent completed.*

510. A. REID and R. TONGE. "Certain improvements in, or applicable to, looms for weaving." Dated Feb. 25, 1859.

This applies to the reed, or that part of the loom by which the weft is struck into the cloth, and it consists in placing the dents or wires of the reed on curved or diagonal lines instead of in a straight line as heretofore. The object is to produce fabrics in which patterns are woven by striking the weft into the cloth in irregular lines. *Patent abandoned.*

511. T. C. HINDS and G. J. HINDS. "Improvements in coating iron with copper, or alloys of copper." Dated Feb. 25, 1859.

In carrying out this invention the iron is first coated with tin, zinc, or lead, or any compound of these metals. It is afterwards plunged into molten copper, or alloys of copper, and subsequently placed in an annealing pan together with fine charcoal dust, or iron filings, or iron borings made by preference from cast iron, and the annealing pan and its contents are then placed in an annealing oven or muffle and subjected to the required amount of heat. *Patent completed.*

512. C. W. SIEMENS. "Improvements in electric telegraphs and apparatus, and in supports for electric telegraphic line wires." (Partly a communication.) Dated Feb. 25, 1859.

The release and stoppage of the clockwork of various descriptions of electric telegraphic apparatus is sometimes effected by the hand of the attendant, and sometimes by contrivances operating by electricity. The patentee here constructs an improved electrical apparatus for this purpose. The invention, which likewise embraces various other apparatuses and numerous details, is not described apart from the drawings. *Patent completed.*

513. W. MCNAUGHT. "Certain improvements in steam engines, particularly applicable to compound steam engines." Dated Feb. 25, 1859.

This consists in applying to the present form of engine, known as a "McNaught's double cylinder engine," a cylinder or cylinders, connected either to the crank-shaft of the engine, or to the engine, through the medium of gearing, the steam being supplied to this cylinder or cylinders in the usual way, and thence passed to the condenser or condensers of the engine or engines. It also comprises other features in connection with the cylinders and condensers of steam engines. *Patent completed.*

514. R. FIELDEN, jun., and T. FIELDEN. "An improvement or improvements in the manufacture of pickers to be used in looms for weaving, and also in the machinery or apparatus to be employed in the manufacture of the same." Dated Feb. 25, 1859.

This invention is not described apart from the drawings. *Patent completed.*

515. J. REDDIE. "An improved mode of propelling and steering vessels." Dated Feb. 25, 1859.

Here the inventor constructs a flexible paddle or rudder of steel plates, or steel, or whalebone, or other elastic ribs covered with gutta serena, &c., so that it may possess the yielding property of a fish's tail. *Patent abandoned.*

516. G. PROVER. "An improved optical instrument, being an improvement upon the kaleidoscope." Dated Feb. 25, 1859.

Here the pieces composing the object are arranged around a rotating shaft mounted horizontally in a box on which the tube of the instrument is secured. In this box is an opening to admit light. *Patent abandoned.*

517. W. CLARK. "Improved apparatus for spinning, twisting, doubling, and drawing fibrous materials." (A communication.) Dated Feb. 25, 1859.

This invention is not described apart from the drawings. *Patent abandoned.*

518. F. WEEKS. "The treatment of certain alcoholic products." Dated Feb. 26, 1859.

This consists in adding to the alcoholic products obtained from beet root, mangold wurzel, &c., essence of cogniac, or other flavouring matters, in order to impart to such products the taste and character of brandy, whiskey, hollands, or gin. *Patent completed.*

519. G. EARNshaw. "The treatment of woollen and other rags and waste of fibrous substances, so as to obtain useful products therefrom." Dated Feb. 26, 1859.

This relates to reducing such substances to a powder or dust, which dust may be used in various manufactures, and consists in subjecting rags to the action of a grindstone or other rough surface in motion. *Patent abandoned.*

520. J. LEE. "Certain improvements in ploughs." Dated Feb. 26, 1859.

The patentee mounts two wheels (the furrow wheel and land wheel) on different axles. The axles are suspended each from an axle or suspension rod. The bottom end of this axle rod is slotted out, and the axle can be set at any part in this slot. The upper ends of these rods have strong spiral springs round them, and pass into, and are suspended from, a frame which is firmly fixed to the beam of the plough. Upon pressure being applied to the wheel, it, along with its axle and axle rod, will move freely in a vertical plane, without acting on the beam of the plough, and on the pressure being removed the springs will force them back to their normal position. By this action, and the slot at the bottom of the suspended rod, the plough will always cut to a uniform depth, and will require scarcely any guiding save to direct the horses. *Patent completed.*

521. J. HINE. "An improved joint for cabinet making, carpentry, and other constructive purposes." Dated Feb. 26, 1859.

This consists in arrangement of grooves or tongues formed upon the edges of the several articles to be jointed together, so as to obtain a more permanent fixed or sliding joint than hitherto, the said joint being employed in lieu of tenons and mortices. The invention is not described in detail apart from the drawings. *Patent completed.*

522. W. BURGESS. "An improvement in reaping and mowing machines." Dated Feb. 26, 1859.

This consists in constructing reaping and mowing machines so as to facilitate their ready turning while in motion; and is particularly applicable to those machines where the inner bearing wheel is in a line behind that of the main wheel. This end is attained by forming a hinge joint behind the finger beam in the side frame to which the small or inner bearing wheel is connected. In consequence of this arrangement an additional side frame is provided to which the upper part of the back framing of the machine is connected. *Patent completed.*

523. E. GATWOOD. "Improvements in buffing, traction, and bearing springs, applicable to railway carriages and locomotive engines." Dated Feb. 26, 1859.

This consists in making spiral or conical shaped steel springs with ribbands of steel rolled with one edge thicker than the other, so that the coil may wedge and fold, one layer within the other, and indeed greater resistance by friction. But to increase the resistance of the springs the patentee applies steel rings or hoops, the ends being open so that the expansion of the spiral spring will be elastically resisted to increase the power. *Patent completed.*

524. F. BRIGNOTES. "The disinfection and rectification of alcohol by the separation of the essential and other oils from the alcohol." (A communication.) Dated Feb. 26, 1859.

This consists in condensing the alcoholic vapour at different degrees of temperature and in separate worms, surrounded by water in worm tubs, the temperature of each being marked by degrees. The invention is not described apart from the drawings. *Patent completed.*

525. A. MARTIN and A. CRICHTON. "Improvements in weaving and woven goods." Dated Feb. 26, 1859.

This consists in the substitution of shedding apparatus in the power loom so constructed as to weave either plain or tweeled cloth, or plain cloth into which is introduced tweeled stripping. The invention is not described in detail without reference to the drawings. *Patent completed.*

526. J. HOWDEN. "Improvements in machinery or apparatus for cutting, shaping, punching, and compressing metals." Dated Feb. 26, 1859.

In a modification of this machinery suitable for making bolts, rivets, &c., the dies are carried by two

circular tables turning about vertical spindles, and upon circular stools or beds. These die tables are placed at each end of the machine, and there is situated between a T shaped lever fast on a shaft turning in bearings formed in the tops by projecting portions of two side frame pieces, constituting the main parts of the framing, and between which the die table stools are bolted. The T lever is made to vibrate by means of a crank shaft working within the lower forked end of the middle or vertical leg of the lever, this crank shaft receiving motion from the driving shaft. The horizontal arms of the T lever are each connected to a vertical heading ram working in a guide carried by a transverse frame piece, also serving to bend the frame together, and the two cams are actuated alternately, the respective die tables being turned between each stroke of each ram to bring a fresh blank round to be shaped. The tables are turned by ratchet movements actuated each from the vertical leg of the T lever by a lever and links, and the T lever is also made to actuate bell crank levers, which at the proper periods push out the bolts or rivets by vertical spindles passing through the bottoms of the dies. A couple of pairs of cutters are arranged at the side of the machine to cut the wood for forming the bolts or rivets into proper lengths, these cutters being actuated by an eccentric on the driving shaft, and being arranged to drop the blanks into a receptacle from which they are taken and placed in the dies. *Patent completed.*

527. J. LEIGH. "Improvements in the purification of coal-gas." Dated Feb. 28, 1859.

This consists in the constant and extensive use of gas-water, in the purification of coal or cammel gas, the object being the removal of various salts of ammonia from the gas. *Patent completed.*

528. G. HORNBY. "Improvements in hackling flax and other fibrous materials, and in machinery for the same." Dated Feb. 28, 1859.

This relates, 1. to a mode of mounting hackles or hackle bars on the belts, straps, sheets, or chains of sheet hackling machines, so that the hackle points will enter the pendant strick or stricks of fibrous material at right angles to a vertical line, or nearly so. 2. To a mode of arranging stripper cocks or slot plates of hackling machines at the bottom sheet, pulleys or shafts being detached from the sheets, and making, when at work, one continuous circular or eccentric movement round the bottom sheet pulleys or shafts to which they are attached. 3. To a certain mode of stripping the tow from the hackles of an extreme fineness. 4. To those machines where two are combined in one, and consists in arranging the troughs so that one is going up while the other is coming down, thereby dispensing with balance weights or springs. 5. It consists in applying a second slide or catch bar for taking out a strick holder from any gradation of hackles, so that the stricks of fibrous material will not get any more hacked than is sufficient for them. *Patent completed.*

529. J. H. JOHNSON. "Improvements in apparatus for stopping horses." (A communication.) Dated Feb. 28, 1859.

This consists of two pressing pads, which are attached to a blade spring secured to the front of the nose-band, and which are caused to approach each other and pinch the nose of the animal at a particular point a little above his nostrils, on tension being applied to a suitable curb rein, which passes through each end of the spring, and through a spring behind the animal's jaws. *Patent completed.*

530. J. H. JOHNSON. "Improvements in apparatus for taking soundings, applicable also to the throwing of life-lines." (A communication.) Dated Feb. 28, 1859.

This consists of a metal tube or casing for containing a requisite number of balls of line placed one above the other, and having the outside end of the line of one ball connected to the inside end of the line of the next ball, so as to connect the whole of the balls. One end of the line is secured to the starting point, and the other attached to the plummet or projectile, the line being discharged as the plummet or projectile descends or advances. *Patent completed.*

531. C. HALL and C. HALL, jun. "Improvements in steam agricultural machinery." Dated Feb. 28, 1859.

This consists, 1, in the use of a single winding drum with a continuous spiral on its periphery, on which the rope for drawing the implement is wound. 2. In the use of an anchor having two circular inclined grooves fitted on the spindle on which the wheel or pulley round which the traction rope passes is keyed. Into these grooves studs or pins on the ends of two levers enter, the inclined grooves being so formed that upon the rotation of the spindle the levers are

caused to move up and down. From the levers depend other vertical levers carrying spring pauls or ratchets which drive ratchet wheels keyed upon a shaft on which a screw is fixed. This screw on being moved enters the soil and drags the anchor after it. 3. In means of taking up the slack ropes in implements used in steam agriculture by the use of two drums loose on the axle of each implement. *Patent completed.*

532. A. TURNER. "Improvements in the manufacture of elastic fabrics." Dated Feb. 28, 1859.

This consists in producing a woollen surface on elastic fabrics by twisting together a fine yarn of cotton, silk, flax, worsted, and fine wool. *Patent abandoned.*

533. A. V. NEWTON. "Improvements in constructing and working condensing engines." (A communication.) Dated Feb. 28, 1859.

This chiefly consists in combining the air-pump and cylinder of a condensing engine, and so applying the cold water injection that condensation is effected in the air-pump, and the use of a separate vessel as a condenser dispensed with. *Patent abandoned.*

534. W. HODSON. "Improvements in rotatory engines." Dated Feb. 28, 1859.

This consists in fitting cylinders with screw-like or other inclined vanes, so that steam entering at one end of a cylinder and passing off at the other, will cause the cylinder to rotate with or on, its axis, as may be arranged. *Patent abandoned.*

535. R. BROWN and W. MILNE. "Improvements in fire-arms." Dated Feb. 28, 1859.

This consists in applying a bolt or stop so as to prevent the hammer striking the cap or priming and thereby exploding it, until such bolt or stop is withdrawn by the combined acts of pressing the butt of the fire-arm against the shoulder, and of passing the hand on a moveable piece in the stock. *Patent abandoned.*

536. E. J. HUGHES. "Improvements in preserving animal food, poultry, game, fish, fruit, and other similar substances." (A communication.) Dated March 1, 1859.

This consists in submitting the above substances to the action of a bath of tartaric acid, and in neutralising the taste of the acid by a bath of bi-carbonate of sodium. The substances are then put into vessels containing boiled water and salt, and the vessels are then hermetically sealed. *Patent completed.*

537. T. CLOAKE. "Stopping of the bodies and wheels of railway and other carriages." Dated March 1, 1859.

This consists of an apparatus whereby the brakeman, at the same time that he applies the breaks of the van, also applies them to the wheels of the other carriages of the train, the break surface of each carriage being so connected by levers that the motion and force applied becomes a thrust between one wheel and the other, so that the force applied to one wheel is the support or abutment of the pressure applied to the other. The power is applied by an upright screw and hand wheel, the screw nut of which rises or falls on such screw, and so actuates the horizontal arm of the lever, by which the power is increased and transmitted to the connecting links and levers of the break surfaces. On one of the levers a pin is mounted which takes the slot of an arm projecting from a horizontal rod carried throughout the length of the carriage, and supported in bearings in which it slides lengthways, the rod of one carriage being connected by a link piece to the rod of the next carriage. The invention also relates to a coupling for connecting railway carriages to each other, which allows a certain amount of play between the carriages, at the same time checking for the most part the violent action and re-action of the buffers when any slight collision occurs. *Patent completed.*

538. J. HOLROYD. "An improvement in finishing woollen cloths, and cloths made from a combination of wool and other materials." Dated March 1, 1859.

This consists in so finishing woollen cloths that an ornamental design is produced upon a plain surface of the cloths. This is effected by cutting the nap shorter in certain parts than in other parts, the whole of the nap after the production of the design thereon being laid in the same direction as heretofore. *Patent abandoned.*

539. Rev. H. MOULE. "Improvements in apparatus applicable to the evaporation of sewage or other waters, and for affording heat for other uses." Dated March 1, 1859.

This consists of a cistern fitted with a suitable arrangement of pipes, and heated by a fire underneath it, by means of which the process of evaporation is effected. *Patent completed.*

540. J. WETHERILL. "Certain improvements in locks." Dated March 1, 1859.

This relates to the "alphabet" or "combination" lock, and consists in so arranging the mechanism thereof as to adapt the same for cash-books, portfolios, trunks, &c. *Patent abandoned.*

541. J. EDWARDS. "Improvements in stacking or holding biscuit, earthen, china, and glossed ware for firing." Dated March 1, 1859.

This consists in the employment for each separate article of a ring frame or holder with a flange projecting inwardly so as to occupy the whole or part of the centre of the ring. *Patent completed.*

542. G. P. RIVERS, BARON RIVERS. "An improved implement for breaking up and preparing land." Dated March 1, 1859.

This consists of a rotary cultivator composed of a drum or cylinder, or of a skeleton drum armed with tines fixed at intervals across the length and around the circumference of the drum. *Patent abandoned.*

543. J. TEMPLEMAN. "Improvements in the manufacture or production of artificial fuel." Dated March 1, 1859.

This relates to a previous patent of the patentee, and consists in the combination with artificial resinous fuel of dried wood, &c. *Patent completed.*

544. J. PILLS. "Improvements in the construction of floating docks." Dated March 1, 1859.

This consists in the use of two sets of pontoons, the one set being kept constantly floated, and the other set being alternately submerged and floated for sinking beneath the bottom of the ship, and of then rising and lifting the ship up with it, the water being pumped out of the submerged pontoon by rotatory pumps or otherwise. *Patent completed.*

545. D. LICHTENSTADT. "Converting certain vegetable substances into fibrous materials for the manufacture of paper, textile and other fabrics." Dated March 1, 1859.

This consists in a process for converting the plant or plants of the genus Bambusa, and Bambusa arundinacea, into fibrous material for the purposes specified in the title of the invention. The details are voluminous. *Patent completed.*

546. J. T. CARTER. "Improvements in machinery for crushing, bruising, and preparing flax, hemp, and other fibrous materials requiring such treatment." Dated March 2, 1859.

This relates to a previous patent of the patentee dated Feb. 1, 1847, and consists in the substitution of the force of buffer or other springs in lieu of the force of gravity of the upper roller. *Patent completed.*

547. P. CURRIE. "Certain improvements in spindles for locks, latches, and other door-fastenings." Dated March 2, 1859.

The patentee claims a method of combining or connecting knobs to locks and latches, so that a perfect contact shall be made and maintained between the base of the neck of the knob, as may be required, and the follow of the lock, or latch, to which the knob or knobs are connected, by which means a positive and agreeable action is imparted to the handle when in use. *Patent completed.*

548. J. VALDA. "Improvements in studs and other like fastenings for dresses, belts, or other purposes." Dated March 2, 1859.

This consists in making the stud in two distinct parts, the face and back of the stud being secured together by spring catches or otherwise. *Patent abandoned.*

549. J. M. ADAMS, D. LAW, and J. INGLIS. "Improvements in fire places, grates, ranges, and stoves." Dated March 2, 1859.

This relates to fire places, grates, ranges and stoves, and has for its object the more effectual carrying out of the system according to which the coal is burned from above downwards, together with convenience of arrangement, and other advantages. *Patent abandoned.*

550. R. H. COLLYER. "A process of preparing materials for the manufacture of paper, and a machine employed therein, which machine is applicable for crushing, grinding, bruising, and reducing various substances." Dated March 2, 1859.

This consists in a method of treating straw, flax, &c., for the manufacture of paper. The straw, &c., is first boiled in water, and then subjected to the action of certain machinery (which we cannot describe for want of space) which opens and breaks it, and prepares it for the subsequent action of caustic alkali; it is then freed from the alkali by washing, and next bleached by steeping it in a solution of chloride of lime. It is finally treated with sulphuric acid and carbonate of lime. *Patent completed.*

551. W. F. DEARLOVE. "An improved chopping machine." Dated March 2, 1859.

This consists of a cylindrical box, the bottom thereof forming the chopping board, the same being made with a flat or curved surface. The top of this

box is susceptible of having a rotary motion imparted to it without detaching it from the box. The knives are arranged so as to cross each other, or are placed at suitable distances parallel to each other. In the interior of the drum is placed a frame provided with teeth or scrapers which free the knives from any substances adhering to them. The chopping is performed by lifting the knives up and down by the handle, the position thereof being from time to time changed by causing the cover of the box to revolve, and thus carrying with it the knives together with the frame before mentioned. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Aug. 6, 1859.

1814. C. C. R. Goudenove and A. Feret. An improvement in gas burners. (Partly a communication.)

Dated Aug. 16, 1859.

1880. W. Leatham. An improved double acting superlative screw throttle valve.

Dated Aug. 22, 1859.

1910. J. Gregory. Improvements in locomotive and other steam-engines.

Dated Aug. 30, 1859.

1970. J. H. Johnson. Improvements in the construction of steam generators, applicable also to the construction of condensers, the heating of water generally, and to the warming of buildings. (A communication.)

1972. G. Collier. Improvements in chairs and couches.

1974. J. Field. Improvements in apparatus for superheating steam.

1976. H. Hutton. An improved lubricator.

Dated Aug. 31, 1859.

1978. J. Cowgill and J. Stocks. Improvements in "caps" for spinning fibrous substances, and in the means or method of manufacturing the same.

1980. W. A. Von Kanig. Improvements in the manufacture of starch and compounds of starch, and in extracting gum dextrine and grape sugar therefrom.

1984. J. Mackenzie and S. T. Wentworth. Improvements in breech-loading fire-arms.

1986. J. Samuel. Improvements in railway-sleepers.

1987. H. Higgin. Improvements in machinery for cutting and preparing match splints.

1988. L. Berge. An improved method of fastening or securing portemonnaies, bags, and other like articles with frames.

1990. E. Ellis. Improvements in finishing silk fabrics made on bobbin net, and warp frames.

Dated Sept. 1, 1859.

1992. J. Brine. Improvements in the mode of preparing, arranging, and combining, the leaves of books to be used for producing simultaneously one or more fac-simile copies of letters, accounts, or other such similar documents or writings.

1996. J. Borington. Improvements in pumps.

Dated Sept. 2, 1859.

1998. P. Wright. An improvement or improvements in the manufacture of anvils.

2002. J. K. Watson. Improvements in gas meters and exhausters, washers, and purifiers.

2004. W. Clough. Certain improvements in machinery or apparatus for propelling vessels on water.

2006. W. A. Turner and H. L. Lilley. Improvements in the manufacture of starch.

2008. J. F. F. Leroux. A new or improved apparatus to be employed for taking money on the counters.

2009. T. Hedgecock. An improvement in quadrants.

2010. J. Spurgin. Improvements in ordnance and projectiles.

Dated Sept. 3, 1859.

2018. G. Parsons. Improvements in wheels.

2020. H. Swan. Improvements in stereoscopes and stereoscopic pictures.

Dated Sept. 5, 1859.

2022. F. C. Bakewell. Improvements in the manufacture of caustic alkalies. (A communication.)

2026. W. L. Earle. Improvements in apparatus for promoting the combustion of smoke and gases arising from fuel.

2024. A. V. Newton. Improvements in sewing machines. (A communication.)

Dated Sept. 6, 1859.

2030. G. Lowry. Improvements in machinery for heckling flax and other fibrous materials.

2034. A. V. Newton. An improved fabric, applicable to the manufacture of hose or flexible pipes. (A communication.)

2036. E. Blake. Improvements in apparatus for and in treating china grass rhos, fibre mudar, and other similar vegetable fibres.

Dated Sept. 8, 1859.

2040. T. Hooman. An improved stock, cravat, or neck muffler, or wrapper.

2051. J. Nicholson. Improvements in horse rakes.

2053. J. Thorley. An improved preparation of food for cattle and horses.

2055. T. W. Alsop. Improvements in portable gas apparatus.

Dated Sept. 9, 1859.

2057. W. Roscoe. An improved agricultural implement or machine for distributing guano and other manures upon land.

2059. J. G. N. Alleyne. Improvements in the manufacture of wrought iron beams.

2061. F. Carpenter. An improved apparatus for cutting tobacco.

2063. S. Cornely. An improvement in the permanent way of railways. (A communication.)

Dated Sept. 10, 1859.

2065. H. O. Robinson. Improvements in machinery or apparatus for the manufacture of sugar.

2067. J. Pollock. Improvements in the manufacture of beds, couches, and invalid or other carriages.

Dated Sept. 12, 1859.

2071. T. G. Gutch. The improvement of copying books, for order books, and letter books, and so forth, as the improvement can be applied.

2075. F. Heindryckx. Improvements applicable to railways or tramways.

2077. F. Veramann and A. Oppenheim. Improvements in the treatment of various substances, so as to render the same noninflammable.

2079. F. N. Gisborne and L. S. Magnus. Improvements in telegraph cables.

2081. H. G. Collins. Improvements in producing printing surfaces on stone, metal, and other materials capable of being employed in printing, in the manner of lithographic stones; also in the production of printing plates and surface printing blocks, and in transfer inks.

Dated Sept. 13, 1859.

2085. G. M. Levi. Improvements in washing and separating ores and substances of different specific gravities, and in apparatus for that purpose.

2087. J. Grainger. Improvements in breech-loading fire-arms, and in moulds for making projectiles.

2089. W. E. Newton. Improved apparatus for drying paper and other fabrics. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Sept. 27, 1859.)

1207. J. M. Munro. Chain harrows.

1224. A. R. Landre, P. Gras, and A. L. A. Boucherie. Distilling.

1231. E. Charlesworth. Fire-arms.

1238. R. A. Brooman. Heating. (A communication.)

1241. G. Walker. Looking glasses.

1247. J. H. Johnson. Calcining ores. (A communication.)

1264. G. Burnell. Medicine for curing ague.

1269. R. A. Brooman. Axles. (A communication.)

1277. G. Davies. Submarine transport. (A communication.)

1278. G. D. Jones. Mills.

1284. A. J. Sax. Wind musical instruments.

1294. J. Mallett. Regulator for time pieces.

1296. J. Howard. Horse-rake.

1300. H. W. Patrick. Substitute for ivory.

1324. M. Davis. Wheels, axles, and boxes.

1341. S. Carr and G. Butterworth. Felted cloth.

1358. S. Bury. Textile fabrics.

1357. S. Bury. Textile fabrics.

1358. W. H. Parkes and W. Bagnall. Hats.

1380. J. B. Pascal. Hot air engines.

1361. J. Wilson. Carbonate of soda.

1390. R. Barclay. Paper.

1406. T. Greenhalghs. Purifying gas.

1412. J. Luis. Syphon meter. (A communication.)

1419. T. E. Tallent. Leather.

1481. D. Deas. Reaping machines.

1487. J. Luis. Windmill. (A communication.)

1511. E. T. Hughes. Artificial stone. (A communication.)

1519. W. Clark. Sewing machines. (A communication.)

1519. W. J. T. Williamson. Gas burners.

1594. W. Knapton and A. Aitchison. Gas.

1602. J. Luis. Wheel tyres. (A communication.)

1689. J. Bailey. Stretching fabrics.

1713. A. Sidebottom. Separating animal fibre from mixed fabrics.

1807. N. Berry. Knitted fabrics. (A communication.)

1870. W. Green and W. and F. B. Fawcett. Edges.
1888. E. Rettig. Anchors. (A communication.)
1972. G. Collier. Chairs and couches.
1974. J. Field. Superheating steam.
1987. H. Higgin. Match splints.
1990. E. Ellis. Silk fabrics.
2006. H. O. Robinson. Sugar.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

LIST OF SEALED PATENTS.

Sealed Sept. 22, 1859.

710. J. Davis.	763. E. Steacie.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 7, 1859.

THE BRITISH ASSOCIATION FOR
ADVERTISING INVENTIONS.

It is all very well, perhaps, to dignify humble things with high-sounding titles, but it is nevertheless desirable that their true nature should be known. There may be nothing very baneful in designating a motley group of men "The British Association for the Advancement of Science," or in enticing the second personage in the realm to pronounce an elaborate eulogy upon it; but at the same time it seems only proper to make known the kind of purposes which the Association seems really intended for. We have no desire to meddle with what does not much concern us, and therefore we say nothing of the Geological, or the Zoological, or the Physiological, or the Ethnological, or any other Section of the British Association which is foreign to our calling; but with the "Mechanical" section we think we have something to do, and therefore venture to make a remark or two upon it.

Now, from an article which we publish on another page, it appears that at the late meeting of the Association at Aberdeen, some four-and-thirty papers (neglecting two Reports of Committees) are said to have been read in this section. About nine of these seem really not to have been papers at all, in the ordinary sense of that term, but were either mere verbal addresses which are not likely to obtain any permanent record, or else remarks written so imperfectly that probably no more will be heard of them. This leaves, then, about five-and-twenty as the total number of the papers communicated to Section G. Of these, six related exclusively to steam navigation, and, although none of the six was calculated, perhaps, to do much of itself in the way of advancing science, it may be hoped that from all of them together—being the productions of Admiral Paris, Admiral Moorsom, Mr. Oldham, Mr. Atherton, Mr. Henderson, and Mr. Elder—some good may result. But if we omit these six papers (all on one subject), we reduce the total number to nineteen; and of these nineteen—and this is the fact to which we wish to draw especial attention—upwards of one-half are very little more than mere advertisements of new inventions—many of them patented, some of them worthless. They comprise descriptions of Mr. Aytoun's patent safety cage for miners, Mr. Robertson's patent chain-propeller, Mr. Clifford's patent boat-lowering apparatus, Mr. Wood's patent apparatus for that purpose, Mr. Clark's patent steam jet for locomotive furnaces, Mr. Allan's gas meters, Mr. Robb's reciprocating propellers, Mr. Rettie's lamp, Mr. Hart's railway gas apparatus, Captain Addison's coal-pit balloons, Mr. Johnson's pressure gauge, some one's patent evaporating pan, and so forth.

Now, we are not about to find fault with the Association for encouraging inventors to do a little business in a respectable way; by no means. We may, perhaps, think it a little strange to find ourselves invited to go all the way to Aberdeen in order to hear a dozen gentlemen read descriptions of inventions which were published months ago, in the form of patent-specifications, and articles in scientific journals. And we may also, perhaps, think it still more strange that we should be invited to go there to hear nonsensical schemes propounded with a total disregard of everything

like scientific reasoning. But these things may be inseparable from the advertising trade.

What we are about to do is to see that, since this so-called Association for the Advancement of Science is in reality (in so far as the mechanical science section is concerned) mainly an Association for the advertisement of inventions, the fact shall be properly made known. And with this view we call the attention of our business readers to the fact. There are about 3,000 inventions patented in this country every year, and as many more, we doubt not, conceived by persons who do not care to patent them. We honestly believe that on the average these inventions are equal in merit to those lately brought to the notice of the British Association. Here, then, is a field for Section G! No less than six thousand papers may be read to its scientific (!) members at the next year's Oxford meeting, and a like supply be repeated for their "advancement" annually! As the section has this year afforded unmistakable signs of barrenness, we doubt not they will pass a vote of thanks to us next year for the suggestion.

But it is not so much in the interest of the Association as in that of inventors and men of business generally that we pen these remarks. We turn to you, ye tradesmen and manufacturers, on whose eyes the "main chance" is supposed to be ever gleaming, and we ask you why are you so blind to this "splendid opportunity?" Why pay us for allowing you to praise your goods on our covers, and yet omit to speak of their merits to the Prince Consort at Aberdeen? Be not so dull next year. Go ye, then, to Oxford, classic Oxford, with your able, imposing papers, and under the plea of the advancement of science practice the science of advancement. Pray feel no delicacy in the matter. You have as good a right to be heard there next year as some whom we have mentioned had to be heard in Aberdeen this year. And we doubt not you will be made welcome. Only avoid being too simple and candid. Remember it is in the name of "Science" that you speak, and therefore omit not to speak largely. Be sure and begin with a grave preliminary dissertation of some kind. You will not find it difficult to do this. The principle of association of ideas will help you. There are plenty of great things in the world to tack little things on to.

Nor should it be forgotten that Section G of the British Association is a very aristocratical body: that is to say, there are many aristocrats who find it amusing to go to its meetings, and sit on its committees, and therefore do so. Only think, for example, of a deputation like that on steam ship performance which this section sent a few months since to the First Lord of the Admiralty, and which consisted of Messrs. McConnell and Scott Russell, and of the Marquis of Stafford, the Earl of Caithness, M.P., Lord John Hay, Lord Clarence Paget, M.P., the Hon. A. Ellis, M.P., the Hon. Captain Egerton, R.N., and Mr. Smith! Such a group going into Whitehall to represent the science of naval architecture must, of course, have been a capital practical joke to those noble lords and honourable gentlemen who took part in the proceeding; and as lords and gentlemen must have their laugh out of something or somebody it is pleasant to see them adopting so very innocent a mode of getting it. But it is to the fact of such persons being present at the Association's meetings that we wish to direct the attention of our business friends. It is not every day that a manufacturer or a tradesman can manage to get a score or two of noblemen and a hundred or two of gentlemen to listen to him while he expatiates upon the merit of his last

new article—his "latest novelty." But he could have done it this year at Aberdeen; he may do it next at Oxford; and he may repeat the process year by year, until the gentlemen of Section G begin to see some glimmering of what science is, and what its advancement means.

A NAVAL LESSON BY A FRENCH
ADMIRAL.

ADMIRAL PARIS, C.B., of the Imperial French Navy, Major-General Maritime of the Port of Brest, in an address on the manœuvring of screw ships delivered at the late Aberdeen meeting of the British Association, has given our naval officers a lesson which they will do well to study. The work on "Naval Warfare with Steam" which Sir Howard Douglas recently published is most usefully supplemented by this speech, in which Admiral Paris has embodied many valuable facts which could only have been acquired by a naval officer in active service. The high standing of Admiral Paris as a scientific officer in his own country, will enable English officers to listen with satisfaction to his observations, while the knowledge that such men as he hold high rank in the French Navy should stimulate them to the most ardent study of every new phase and ramification of their profession. Such men as Admiral Paris will play a most important part in future naval wars, and it is to be hoped they will not be without many rivals in our own service. Those observations of his to which we are about to refer, although necessarily somewhat technical, are of a most interesting kind, and will doubtless help to awaken many an officer to a better sense of the value of screw ships of war than he has hitherto possessed.

The gallant officer commenced his observations by pointing out the fact that the propelling properties of the paddle and the screw are very different according to the form, mode of acting, and especially the position of the propellers in the ship. A few words will show these differences, and will enable us to deduce the special qualities of each propeller, and thence the method of making a good use of them for the various purposes of navigation. In what follows we shall endeavour to adhere as closely as possible to the translation of the Admiral's speech with which we have been furnished. The paddle acts, as is well known, at or near the surface of the water, and forces it in the direction of the keel when working either ahead or astern. The current produced by the resistance of the water is useless to the rudder, because it acts only on the upper part, where the rudder presents no flat surface. Moreover, the action of the paddles will not affect the ship's course, unless one is immersed more deeply than the other, thus meeting more resistance, or, as is provided for in the case of some tugs, when one acts in one direction and the other in the reverse, thus causing the ship to turn. The screw, on the other hand, acts on the water by a twisted surface, which, instead of pushing back the water in the direction of the keel, gives it a whirling motion, and projects it abaft in the shape of a cone. The screw produces a current in the same way that the paddle-wheels do, but being much below the surface of the water, and just ahead of the rudder, the latter receives the impulse of this artificial current, which acts before the vessel has moved, her inertia causing her for a few minutes to resist the impulse of the propeller. Hence, a principle is deducible, viz., that a paddle-wheel vessel cannot steer without moving, and that on the other hand a screw vessel will steer before moving, and that even long

after the propeller is at work if any obstacle resists its translating action.

Another difference arises from the action of the screw, because its blades are oblique to the length of the ship, and they are pushing the stern not only ahead or astern, but also sideways, so that if the water were equally resistant close to the surface and below it, the equilibrium of both vertical blades would make the screw act equally throughout its path. But this is not the case, and the water being more resistant as the depth increases, the lower blade moves with more difficulty than the upper one, and the stern is acted upon sideways in proportion to this difference in the resistances, so that the ship will not move directly forward, but, if the rudder does not balance this effect, will deviate always to the same side. This effect will naturally be more or less energetic according to the immersion of the screw and the length of pitch; for if the screw-shaft were at the level of the sea and the pitch infinite, that is, if the blade were in the plane of the axis, the stern would only be forced round, and the vessel not propelled. Consequently, in the actual state of things, the action of the screw on the stern is compounded of the propelling and of the lateral effect. This cannot be avoided, and can only be lessened by an increase of immersion, or by a reduction of the pitch. A right-handed thread deviates the ship to larboard when going ahead and to starboard when going astern: it is the reverse for a left-handed screw.

From these considerations, says Admiral Paris, "it would appear at first sight that the paddle acts much better in making a ship steer well than the screw, and that the disturbances caused by the screw on the ship's way presents obstacles to the management of the ship; but it is not so, and these properties of the screw may be used in such a way as to manœuvre in various ways impossible with paddles." If, for instance, it is desired to turn a vessel short round at the moment before raising anchor, a paddle-vessel will want ropes, or at least sails if the wind permits, and her propeller will be used only to resist the wind, or to act in the direction of the keel. The screw, however, enables her to turn round on the same place even in a calm, for if she moves gently ahead with the anchor still holding on, the screw, by thrashing on the rudder, makes it steer the ship as though she were under way. This is well known, many vessels adopting this plan in order to acquire the right direction without moving ahead, and the moment that this is attained weighing anchor and going ahead. If she is not at anchor, a screw-vessel may be made to turn on herself, by the help of her own inertia. Thus, let the screw work back and the ship will begin to turn her head to starboard, and when she has gone half her length reverse the engine at an increased speed with the helm a port. The ship will then move ahead, still turning to the same side; and by repeating the same operation several times the turn of the whole horizon will be made in a much shorter time than would at first be supposed, and the space required to turn in will be dependent on the duration of each operation. If there is any wind the sails may be used to accelerate the evolution, either by their oblique action on the ship by the aid of the jib or mizen sail, or by increasing the speed of the screw and backing the sails. These manœuvres of screw-ships, which are manifestly of the highest importance—especially for war ships, which may require to change position in action—have often been performed, says Admiral Paris, and have enabled such ships to thread their way amongst crowded shipping in a space

which would have been far too confined for a paddle or sailing ship acting without the help of hawsers.

Again, ships are often required to remain in one position without casting anchor; now, with sails, as with paddles, there is always leeway, and the ship cannot stand on unless with a beam wind. There is also a difficulty in taking another ship in tow, and as large ships require much time in sending their tow-ropes on board, they are generally obliged to drop anchor and then weigh again when the second is in tow. This is a very long operation, and can easily be avoided by making use of the before-mentioned properties of the screw when the wind is either ahead or astern. "Let us suppose, firstly," says the Admiral, "that a vessel is intending to take in tow another lying at anchor. She will sheet and hoist her mizen topsail and top-gallant sail according to the wind, place herself at a short distance ahead of the other, and work her engine slowly. Thus, the backing force of the mizen sails would be compensated by the heading one of the propeller, and the ship acted upon by these two equal and opposite forces will remain motionless; but she will steer as well as if making way by means of the artificial current before spoken of, and she will change her position or remain exactly motionless, and without any deviation of her head, as long as may be required. I have done this several times when ordered to take ships in tow, and remained once more than twenty minutes with scarcely any change of position or direction." This combination of the propelling powers of both sails and the screw may also be employed in maintaining the ships with an oblique direction of the wind, two or three points, for example, by bracing properly the mizen topsail; but then there is a slight leeway, and if the wind blows in the direction of the beam it is the usual condition of sailing or paddle-vessels standing on.

Further, it is very often useful to be able to back a vessel in any direction, and when he can do this a captain will dare to go anywhere. With a paddle-vessel this is possible for short distances, combined with the help of some sails; but with the screw alone it is impossible, owing to the side action above named: so in a calm a screw-ship cannot follow by her stern the same way she made by her head; she must have room enough to turn on herself. Again, suppose a vessel is required to remain in the same place, with the wind astern. She hoists her fore-topsails, and works her screw back; these two forces can be balanced by the throttle valve, and their propelling action brought into equilibrium. But the screw deviates the vessel to starboard, and this can be avoided by hauling on the larboard braces of the fore-topsail, so that not only the pushing actions but also the deviating ones are entirely balanced. "I have remained at rest by these means several times," says Admiral Paris, "and once for an experiment for half an hour; it was on board a frigate, 76 metres, or 226 feet long; she changed her direction only one point and a half of the compass, and varied in her position only the distance between two ports; with more attention she would have been exactly motionless." If it is wished to make stern way, it is very easy to work the ship to accomplish this, by ordering the screw to work quicker, at the same time bracing the fore-topsail somewhat more; thus the latter will not push too much ahead, and will balance better the deviating action of the screw. "By this method," he says, "on board the same frigate I went astern at a speed of three knots, and with a deviation of one point in half an hour. The ship was steered as exactly by her fore-

topsail properly braced as by her rudder when going ahead, the only attention required being to proportionate the work of the screw to the action of the fore-topsail, and to back slower when the wind is light."

From these remarks it will be concluded that the screw ship is more handy than the paddle, not only because she steers better, but also because the deviating properties of the propeller are variably and usefully employed. This leads the gallant Admiral very naturally to anticipate that the Great Eastern will be the most handy vessel afloat, if the properties of the two propellers are usefully employed. In reality she has in her paddle engines the equivalent of a good and constant head wind, which can be used with an admirable exactness; so that if she is required to turn round on herself, let the paddle turn astern and the screw ahead; the equilibrium of these two forces will be soon obtained by giving a quicker or slower motion to either of the propellers. The artificial current against the surface of the rudder will be thus obtained without any motion of the ship, and she will turn herself very easily. The motion will be accelerated at pleasure by working the propellers with more or less energy, but always equally, which is easily obtained by looking at some point on shore, or the water alongside, and adjusting the throttle valves properly. But that is not all; she will steer even when making way astern, which would be impossible in any other vessel, unless with a good breeze acting on the topsail; for, suppose the power of the screw to be overcome by that of the paddles, the ship will go astern, but still preserve the artificial current necessary to steer, and it will be a matter for experiment to find out the proportion of the maximum of back speed at which the ship will steer, that is to say, the minimum of screw power to be employed in proportion to the paddle. This being known by experiment, the Great Eastern could go up the Thames to her moorings stern first, and steering as steadily as if she were head first; should the latter be preferred, the properties of the united propellers will still be useful; thus, if it is wished to keep her steering short without making much way, the paddles should be backed sufficiently to balance the screw, and keep the ship at two or three knots, or less, if wanted, whilst the screw is turning so as to give a speed of ten or twelve knots, and so that the helm will have an energy unknown on board any other ship, and will not be subject to the influence of tides or currents. The Great Eastern would therefore go to her moorings either head first or stern first with greater facility and security than many ships of common dimensions but moved by a single propeller.

"Being a seaman, my thoughts were naturally directed," said Admiral Paris in conclusion, "to the method of making good use of the means put into the hands of a captain by the skill of the engineers who invented and made the various engines. So, from one trial to another, and reflecting on the principle of the action of the screw, I arrived at a new theory on the manœuvres of these kinds of ships; and to illustrate the difference of their management from that of paddle vessels, I have arranged in two columns in my catechism for seamen and steam engineers the answers to questions on this subject, which greatly facilitates the comparison; the left column for paddles and the right for the screw. A chapter of 100 octavo pages has been devoted to the elaborating the details of these practical means of managing screw ships as easily as a horse, and to expose in a clear manner the variety of methods employed with each pro-

"peller to make any manœuvre requisite in intricate navigation, and especially on leaving or entering crowded harbours. I should have been glad to see these methods experimented on, or have used them myself if permitted, on board the Great Eastern, as this ship is the most interesting problem of modern navigation, and one which involves not only the speed, distance, and economy of transport, but also the means of manœuvring with facility and security this tremendous body, the largest ever created by man to be moved on the seas."

HEARDER'S SUBMARINE TELEGRAPH CABLE.

THIS novel and interesting application of scientific research to the removal of a difficulty that threatened to circumscribe the limits of success in submarine telegraph cables, and which has excited of late considerable interest in the minds of telegraph engineers, was last week submitted by the inventor for the approval of the judges of the Royal Cornwall Polytechnic Institution, at their annual exhibition held at Falmouth. Their entire satisfaction with the efficacy of the plan, and their perfect concurrence in the soundness of Mr. Hearder's scientific reasonings, were manifested by the unanimous award of the Society's first class silver medal. Of the many modifications of which Mr. Hearder's plan for obviating the effects of induction is susceptible, he appears to have selected the following:—The wire strand, which is five or six times as large as that of the Atlantic cable, is first coated with a number of strands of a very superior flax twine, incorporated with an adhesive insulating medium, which binds them firmly together. They are laid on in a very long spiral direction, the reverse of the twist of the wire; this is secondly coated with a layer of gutta-percha, and, thirdly, with another layer of twine laid on in the same manner, but in a direction opposite to that of the first. The whole is subsequently covered with two layers of gutta-percha. In other samples the first layer of twine next the wire is omitted, and one or two layers of twine and adhesive composition are laid on after the first coating of gutta-percha, and are subsequently covered with two thicknesses of gutta-percha.

Mr. Hearder's patent mainly consists in the employment of fibrous materials between the wire and the insulating medium itself. The advantages of it are stated by Mr. Hearder to be—1st. The reduction of the disturbing influences of inductive action to a minimum upon well-recognised electrical principles, which have been submitted to the test of experiment. 2nd. Improved insulation: the heavy hydraulic pressure to which the submerged cable would be subject, not only prevents the possibility of fissures occurring in the adhesive insulating composition, but any fissures in the gutta-percha itself would be effectually filled or closed over by this composition, thereby rendering the chance of leakage from damage, resulting from rough usage to the cable, infinitely less than with gutta-percha alone. 3rd. Increased strength: every strand of twine possesses a breaking strain of about 40 lbs., consequently, as the samples contain from 25 to 50 of these strands it is evident a breaking strain of from 1,000 to 2,000 lbs. is added to that already possessed by the cable itself without the twine. 4th. Extreme lightness: the specific gravity is from 1.3 to 1.4, varying with the size of the conducting wire. 5th. Perfect facility of recovery after submersion: as the cable will support a weight five times greater than that of any portion of its length which can be submerged in depths available for telegraphic pur-

poses, its recovery after submergence is certain and easy. With such advantages as these, it may fairly be asked, what possible objection there can be to its immediate general adoption by telegraph companies and engineers?

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

At the annual meeting of the British Association for the Advancement of Science, lately held at Aberdeen, the following papers were received in the Mechanical Science Section (Section G.), of which the Rev. Professor Willis, F.R.S., was the President.

THURSDAY, Sept. 15.

1. Report of the Committee on Steam Ship Performance. [We have been favoured with a copy of this report, and if we can extract anything useful from it for our readers, will not fail to do so.]
2. Admiral Moorsom.—On the Performance of Steam Vessels. [A copy of this paper has not yet reached us; we may state, however, that it consisted mainly of statistics.]
3. J. Oldham, C.E.—Report of the Progress of Steam Navigation at Hull. [This paper is published in our present number.]
4. Charles Atherton, communicated by H. Wright.—On Mercantile Steam Transport Economy, as affected by the Consumption of Fuel. [We have been favoured with a copy of this paper, and shall either publish or notice it in an early number.]
5. J. Macquorne Rankine, LL.D.—A Condensed Abstract of Experiments, by Messrs. R. Napier and Sons, on the Strength of Wrought Iron and Steel. [This paper will be published in an early number.]
6. Donald Bain, communicated by H. Wright.—On Harbours of Refuge. [This seems to have been a speech rather than a paper; at any rate we can at present get no report of it.]

FRIDAY, Sept. 16.

1. P. Le Neve Foster.—Report of the Patent Committee. [Published in the MECHANICS' MAGAZINE for last week (Sept. 30).]
2. William Fairbairn, F.R.S.—On Experiments to determine the Efficiency of Continuous and Self-acting Breaks for Railway Trains. [This paper is published in our present number.]
3. J. F. Bateman, C.E., F.R.G.S.—Description of Glasgow Water Works. [This was a verbal description of drawings, of which no report has reached us.]
4. R. Aytoun.—On a Safety Cage for Miners. [This was, we believe, a description of an invention recently patented by the author, the specification of which has been published in due course by the Commissioners of Patents.]

SATURDAY, Sept. 17.

1. J. F. Bateman.—On the Result of Boring for Water in the New Red Sandstone near Shifall, in the County of Salop. [This is published in our present number.]
2. W. Robertson, communicated by Peter Spence.—On a Patent Chain Propeller. [We have a copy of this, and will publish it if we find it of sufficient interest.]
3. Admiral Paris, C.B.—On the Manœuvring of Screw Vessels. [This is abstracted in a leading article of our present number.]
4. Arthur Taylor, communicated by H. Wright.—On the True Action of what are called Heat Diffusers. [This will be published in an early number.]
5. A. Batten.—On a Boat-Lowering Apparatus. [This was a paper on Mr. Clifford's apparatus; we hope to find space for it hereafter.]
6. E. A. Wood.—On a Mode of Suspending, Disconnecting, and Hoisting Boats attached to Sailing Ships and Steamers at Sea. [This paper was not, we believe, read. We may state, however, that it consisted mainly of a description of the apparatus described and illustrated at page 105 of the MECHANICS' MAGAZINE for the 12th of August last.]

7. D. K. Clark, C.E., communicated by H. Wright.—On Smokeless Coal-burning Locomotive Engines. [This is published in our present number.]

MONDAY, Sept. 19.

1. Abbé Moigno.—On a New Gas-burner.
2. Abbé Moigno.—On an Automatic Injection for Feeding Boilers, by Mr. Giffard.
3. Abbé Moigno.—On a Helico-meter, an Instrument for Measuring the Thrust of the Screw Propeller.
4. Abbé Moigno.—On an Application of the Moving Power arising from Tides to Manufacturing, Agricultural, and other Purposes; and especially obviate the Thames nuisance. [The above four papers were written in too imperfect English to find a place in our pages.]
5. Alexander Gibb.—Description of the Granite Quarries of Kincardineshire. [We have a copy of the paper, which we may perhaps publish in an early number.]
6. { Alexander Allan.—On Gas Meters.
Alexander Allan.—Description of an Improved Method of Obtaining a True Liquid Level. [We have a copy of this paper, but not (at present) of the drawings which illustrated it.]
7. John Robb.—On the Comparative Value of Propellers. [This paper, however fit for the British Association it may have been, has no sort of claim to be published in our columns. The invention advocated in it is a very old one, and the views of the author are not such as to help it at all.]
8. Alexander Gerard.—An Experimental Illustration of the Gyroscope. [This does not admit of publication.]

TUESDAY, Sept. 20.

1. William Fairbairn.—Experimental Researches to Determine the Density of Steam at Various Temperatures. [An abstract of this paper will be published in an early number.]
2. J. Elder.—On the Steam Machinery of the Callao, Bogota, and Lima. [We have a copy of this, which we may publish in an early number.]
3. J. P. Joule, LL.D., F.R.S.—On Surface Condensation. [This was little more than a memorandum; no copy of it has yet reached us.]
4. Mr. Rettie.—On a Submarine Lamp. [An abstract of this will be published in an early number.]
5. G. Johnstone Stoney.—On the advantages of the 40-inch Metre as a Measure of Length. [This is published in our present number.]
6. Andrew Henderson.—On India River Steamers and Tow-boats—giving an account of their improved construction for light draft, capability for cargo, and fittings, conducive to manageability in shallow rapid rivers, &c., and of the practical value of the Dynamometer in showing the resistance of vessels in tow, at different speeds and loads, with the result of tests made in England. [We have not yet received a report of this paper, but have been informed that it is in the main a résumé of what Mr. Henderson has before read and published on the same subject.]
7. G. Hart.—On Gas Carriages for Lighting Railway Carriages with Coal instead of Oil. [This paper describes a method by which coal-gas may be applied to railway carriages. The author does not seem to be aware of what has been before proposed and done in this respect. We will, however, publish it if we find it will be of any value to our readers.]
8. Captain J. Addison.—On Coal-pit Accidents. [This paper recommends the carrying out of an idea which occurred to the gallant author on seeing a man vending children's balloons in the Rue de Rivoli, Paris, viz., that of employing similar balloons to test the atmosphere of mines, the presence of carburetted hydrogen being detected by the balloons not rising to the top of the mine, chamber, or passage, and the presence of carbonic acid by their not sinking to the bottom.]
9. H. Johnson.—On a Deep-sea Pressure Gauge. [We have a copy of this paper, and shall publish it in an early number.]
10. Mr. Davies, F.R.S.A., F.L.S.—On a Patent

Disc Pan for Evaporating Saccharine Solutions and other Liquids at a Low Temperature. [We shall probably publish this in an early number.]

11. Adam Topp.—Various Modes of Fire Escapes, Boats, &c. [This miscellaneous affair has not reached us in any form.]

There were a few papers which will be of interest to our readers read in other sections of the Association; these we shall publish in due time.

ON EXPERIMENTS TO DETERMINE THE EFFICIENCY OF CONTINUOUS AND SELF-ACTING BREAKS FOR RAILWAY TRAINS.

By WILLIAM FAIRBAIRN, C.E., F.R.S., &c.*

OF late years various improvements have been introduced upon railways, to diminish the dangers of travelling, and attention is now specially directed to the increase of the retarding power for trains by various kinds of breaks. From an early period in the history of railways, it was seen that few objects were more important for ensuring the security of passengers, and reducing the loss of time occasioned by stoppages, than the attainment of some means of destroying the momentum of trains with ease and rapidity: that is, in the least time and in the shortest distance. The less the time requisite to break a train, the longer the steam may be kept on in approaching a station and the less is the loss of time in stopping. And the shorter the distance in which a train can be brought to a stand, the less danger is there of collision with obstructions on the line perceived not far off ahead. It is already allowed by many of those connected with railways, and has been expressly stated by the Lords of the Committee of Privy Council for Trade, that the amount of break power habitually supplied to trains is in most cases insufficient, and their Lordships enumerate thirteen accidents from collision occurring in 1858, the character of which they consider would have been materially modified, if not altogether prevented, by an increased retarding power under the command of the guards of the trains.

Upon this subject the most important communication hitherto made has been the Report prepared by Colonel Yolland for the Railway Department of the Board of Trade, and containing a large number of experiments with heavy trains at high velocities. The breaks with which Colonel Yolland experimented were those which, as improvements on the common hand break, have hitherto commanded most success. These were the steam break of Mr. McConnell, the continuous break of Mr. Fay, the continuous and self-acting break of Mr. Newall, and the self-acting buffer break of M. Guerin. The general conclusions to which Colonel Yolland was led by his experiments resulted in the recommendation of the break of Mr. Newall; and for heavy traffic, a provisional recommendation of the break of M. Guerin.

From a misunderstanding caused by this Report of Colonel Yolland arose the necessity for some further experiments on the similar breaks of Mr. Fay and Mr. Newall; and these I was called upon to arrange and carry out, by the directors of the Lancashire and Yorkshire Railway. I propose to lay before the Association a brief abstract of these experiments, with some remarks upon the conclusions to which they gave rise.

It will not be necessary here to describe minutely the details of the construction of these breaks. They consist essentially of a series of break blocks acting upon every wheel of the carriages of the whole train or some part of the train, the break blocks being suspended as flaps or placed on side bars beneath each carriage, as in the ordinary arrangement of the guard vans. But whereas it would be both expensive and inefficient to work these breaks with a guard or breaksman to each carriage, both Mr. Fay's and Mr. Newall's patents provide for a continuous shaft, carried the whole length of the train beneath the framing, and with suitable jointed couplings between each

pair of carriages, so that they may be undisturbed by the rocking motion of the train or the action of the buffers. In this way the whole of the breaks may be worked by a single person at either end of the train communicating his power to each break through the agency of the continuous shaft.

Again, there have been applied, in the first instance by Mr. Newall and subsequently by Mr. Fay, powerful springs beneath each carriage, connected with the arms of the rocking shaft, by means of which the breaks are made to act instantaneously throughout the train, on the release of a catch or disengaging coupling in the guard's van. The value of this provision for the immediate and simultaneous action of the whole of the breaks, in cases where an obstruction is perceived upon the line, will be at once evident. It is one of the most important features of these breaks.

In carrying out the views of the directors of the Lancashire and Yorkshire Railway Company, it was arranged, in order to test the relative efficiency of these breaks, to have a series of experiments upon the Oldham incline of 1 in 27 on this gradient. A train of carriages fitted with Mr. Newall's self-acting slide breaks, and a similar train fitted with Mr. Fay's continuous flap breaks, were started in turn, and after having passed over a measured distance by the action of their own gravity, the breaks were applied, and the distance along the incline in which the trains were respectively brought up was carefully ascertained, as a measure of the retarding force of each. The trains employed consisted of three weighted carriages each, and having been placed upon the incline, they were started by removing a stop. Having then descended a previously measured distance with a uniformly accelerating velocity, they passed over a detonating signal, which conveyed notice to the guard to put on the breaks. Then the train having been brought to a stand, the distance from the fog signal to the point at which the train stopped was measured, and the train brought back for another experiment. In this way it was easy to obtain an initial velocity of 50 feet a second, or 35 miles an hour, before applying the breaks.

Unfortunately the day upon which these experiments were made proved misty and foggy, with rain at intervals, so that the rails were in the very worst condition for facilitating the stoppage of the train. The significance of this fact will be seen on comparing the retarding power of the breaks in these experiments with those made in fine weather.

Reducing the results, we find that the retarding force exerted by each break in terms of a unit of mass, was equivalent to the numbers in the following table:—

EXPERIMENTS ON THE OLDHAM INCLINE.

No. of Experiment.	MR. NEWALL.			MR. FAY.		
	Velocity of train in stop- ping in feet per sec.	Time in seconds.	Retard- ing force of break.	Velocity of train in stop- ping in feet per sec.	Time in seconds.	Retard- ing force of break.
1	25.71	14	1.32	25.71	13	1.91
2	30.00	16	1.63	30.00	13	1.70
3	37.50	17	1.70	37.50	14	1.84
4	42.85	25	1.69	41.37	15	1.76
5	42.85	14	2.01	40.66	12	2.02
6	48.39	19	1.78	48.38	25	1.72
7	52.91	17	2.04	50.00	17	1.91
Mean	31.6	17.4	Mean	39.2	18.5	

The general result of these experiments gives a retarding force of 1.71 lbs. per unit of mass for Mr. Newall's break, and 1.85 for Mr. Fay's. Or, in other words, Mr. Newall's break exerted a retarding force of 121.3 lbs. per ton weight of the train, and Mr. Fay's a retarding force of 129 lbs. per ton.

I afterwards arranged for some further experiments at Southport upon a piece of level rail between that town and Liverpool. The speed requisite in this case had to be obtained by the aid of an engine, which was detached by a slip coupling at the instant of applying the breaks.

In other respects these experiments were conducted like the preceding, with fog-signals, and the time noted by stop watches. The weather, however, was in this case fine and dry, and hence the following results were obtained in the most uniform circumstances.

The friction of the train itself, and the resistance of the air, was ascertained to amount with Mr. Newall's train to 6.4 lbs. per ton, and with Mr. Fay's train to 10.4 lbs. per ton.

EXPERIMENTS AT SOUTHPORT.

Slide breaks; Engine detached.

MR. NEWALL.			MR. FAY.		
Speed in miles per hour.	Distance of pulling up in yards.	Retard- ing force of break.	Speed in miles per hour.	Distance of pulling up in yards.	Retard- ing force of break.
32.72	56½	6.77	35.29	56	7.97
33.73	77	6.28	43.90	93	7.05
43.90	136	5.08	50.00	129	6.94
44.15	140½	5.42	51.54	144	7.49
52.91	205½	4.80	54.54	161½	6.39
54.34	192	4.68	57.80	97	5.30
47.37	205½	5.23	60.00	204½	6.80
53.73	222	5.23	60.00	214	6.03
63.16	273	5.53			
Mean		5.49	Mean		6.70

In this case we have a retarding force per unit of mass equivalent to 5.49 lbs. in Mr. Newall's break, and 6.7 lbs. in Mr. Fay's. Or, in other words, the retarding force of the slide breaks of Mr. Newall, from eight experiments, at velocities varying from 35 to 60 miles an hour, was equivalent to 382.6 lbs. per ton weight of the train. The retarding force of Mr. Fay's slide break from eight similar experiments, at velocities from 33 to 63 miles per hour, was equivalent to 466.4 lbs. per ton weight of the train.

FLAP BREAKS—ENGINE DETACHED.

MR. NEWALL.			MR. FAY.		
Speed in miles per hour.	Distance of pulling up in yards.	Retard- ing force of break.	Speed in miles per hour.	Distance of pulling up in yards.	Retard- ing force of break.
50.00	132½	6.73	51.43	158½	5.93
50.00	123	7.28	51.43	162½	5.82
51.43	192	4.93	54.54	184	5.79
Mean		6.32	Mean		5.87

These experiments give for the retarding force of Mr. Newall's flap break 6.32 lbs. per unit of mass, and for Mr. Fay's, 5.87 lbs.

Or, in other words, the retarding force of Mr. Newall's flap break, from three experiments at velocities varying from 50 to 51½ miles per hour, was equivalent to 440.3 lbs. per ton weight of the train.

The retarding force of Mr. Fay's flap breaks, from three similar experiments, was 408.6 lbs. per ton.

We may illustrate the general bearing of these experiments by estimating from an average of the whole experiments the distance required to stop a train fitted with these breaks, and detached from the engine:—

A train would be stopped at a velocity of

20 miles an hour in	23.4 yards.
30 " "	52.9 "
40 " "	93.8 "
50 " "	146.8 "
60 " "	211.5 "

This last table exhibits, in a very clear manner, the advantages of this class of breaks, in which the whole weight of the train aids in destroying the momentum of the mass instead of the weight of one or two guard vans only. It may be impossible in long trains to apply these breaks to every carriage; but at all events, in the ordinary traffic, three times the present amount of break power may be employed with ease.

On the score of economy, also, the system appears to encourage its application. From experiments which have been made it appears that the wear of the tyres is far more uniform and equal, because the springs may be so adjusted as not to cause the wheels to skid. The manager of the

*A paper read to the British Association, 1859.

East Lancashire Railway states that with two trains running together between Salford and Colne, the carriages fitted with continuous breaks travelled 47,604 miles before the wheels required turning up; whilst an ordinary break van, running the same distance, had to have its wheels turned up three times in the same period, three-eighths of an inch being taken off each time.

EXPERIMENTS AT SOUTHPORT.

Engine not detached from the trains.

MR. NEWALL.		MR. FAY.		Remarks.
Speed per hour.	Distance of pull-ing up.	Speed per hour.	Distance of pull-ing up.	
Miles.	Yards.	Miles.	Yards.	
33-96	124½	31-8	121½	} Engine and tender. } Tender break appld. } Tank engine.
37-11	109½	33-96	137	
41-86	221	41-86	192½	
		51-43	274	

It will be observed that on most through lines that the trains travel on some portion of the distance at the rate of 60 miles an hour; and in the event of an obstruction half-a-mile in advance a collision would be inevitable unless the driver has the power and the presence of mind to act with promptitude. Now, at 60 miles an hour there is only 30 seconds, or half-a-minute, to effect that object, and it is quite impossible to apply the breaks in their present state before the train—in such a precarious position—is in actual contact. Assuming, however, that breaks upon the principle of Newall and Fay were attached to the engine as well as the train, and that the driver had the power of instantaneous application by liberating a spring, it is evident that instead of the train dashing forward to destruction, the momentum might be destroyed in a distance of less than 500 yards, and that without injury to life or property. Besides, the application of the electric telegraph, which prevents on most through lines more than one train being on the line between the stations, is a great additional security, and that united to the continuous break *applied to the engine as well as the train* would, when united to a more perfect system of signals, render collision next to impossible.

ON THE SUPPLY AND PURIFICATION OF WATER.

By THOMAS SPENCER, Esq., F.C.S., &c.*

THE author of this paper set out by stating that from an extended practice for a number of years in relation to the chemistry of water for the supply of towns, he became convinced that the available quantity of pure water in these islands was decreasing, whilst it was evident the demand for this primary necessary of life was undergoing an annual increase. In short, that in the more cultivated districts the supply was every year becoming less capable of meeting the demand.

From continuous personal observation of many of the water-bearing districts of Great Britain, he had now found many shallow springs dried up, or gradually becoming so, whilst the beds of small streams, where water was formerly known to flow pretty regularly, were almost dry, except in times of flood. This had a corresponding effect on the depth of the water of most rivers, but was especially felt of late years in those that were navigable.

The bearing of this state of things on our available water was to increase the quantity of its organic impurity, inversely with the amount of its supply. These effects he would show were chiefly due to increasing drainage.

An additional and most important source of the impurity of river water arose from the now legalised efflux of excremental matters into common sewers, and thence into rivers, by which they were rendered equally fertile sources of disease to the cesspools they had superseded. In short, wherever population was, running waters were becoming more and more polluted with the

matters which formerly went to maintain the fertility of the soil. Nor was it necessary to remind the members of that section that agriculturists had to resort to another hemisphere to make up the deficiency. So obvious had this evil become, that the aid of chemistry had been universally called for to devise some means of entrapping the riches which were thus squandered in the ocean.

Although prophecies as to the results of contemporaneous operations were attended with considerable risk, yet he would venture to predict, that the chemical efforts now being made to utilise sewage matters must prove abortive, simply because they were commenced at the wrong end of the sewer. That modes were known to chemists fully equal to the extraction of all the nitrogenous and phosphoric constituents of diluted sewage, there could be no doubt.

The real question, as regarded any of these operations, was not as to whether it *could* be done, but whether, when done, the products would repay the cost of obtaining them—a consummation which was far from probable. At the same time the chances of success would be found much greater if the attempts to utilise these matters were undertaken at less distance from their source, and previous to what he regarded as their *destructive dilution with water*. As it was, however, this had the effect of causing the inhabitants of towns to resort to distant quarters for water, to replace that which they formerly obtained in sufficient abundance from the rivers.

As already stated, shallow springs were becoming extinct, whilst supplies from wells could only be obtained by carrying them to greater depths, and those had to be sunk far apart, to ensure an extended conoid of percolation. Mr. Spencer then proceeded to show that the causes of this general diminution of spring water was almost entirely due to the vastly increased drainage that had taken place of late years. The greater part of the rain that was formerly allowed to percolate the substratification, and thence issue at lower levels as spring water, was now carried off the land by means of deep drainage, and drain pipes, into the adjoining brooks in a few hours. The contrast between this and the former state of things was described as being not unlike that witnessed after rain had fallen on two roofs, the one thatched, the other slated. For hours after the last shower water trickled from the eaves of the thatch, whilst a few minutes served to obliterate all traces of moisture from the slates.

But in addition to this, the same condition of things had the important effect of diminishing our rainfall as well, so that not only was it rapidly carried off the land, but as a direct consequence, every year drainage had less water to deal with. This result arose as follows:—The larger amount of dry surface resulting from excessive drainage had two distinct effects, each dependent on the other. One was to diminish the amount of evaporation, and thereby cause fewer clouds, whilst the same absence of moist surfaces prevented clouds from other quarters being attracted, consequently their aqueous contents were not so liable to be discharged on the now well-drained tracts as formerly.

Though the operation of these circumstances on our climate was described at considerable length, yet this part of the subject was alone so extensive as to cause the author to leave many important points untouched. In concluding the first part of his communication, that he might briefly exemplify the principles he had set forth, Mr. Spencer put it to his auditory, if, when speaking of formerly moist or ill-drained districts in recently discovered tracts, they did not constantly hear of the *meliorating influence* which had been effected on climate by cutting down forests, and draining marshes, and, *was not this always followed by a lessening of rainfall?* And again: if these sources of evaporation were thus cut off, was it not obvious that the natural process of cloud-forming must to that extent be decreased, and therefore less rain be likely to fall? Besides,

were not most observers agreed in opinion, that clouds are attracted wherever there is wide-spread moisture, and as a consequence, is their rain not discharged more abundantly and frequently at those parts of the surface, than where moisture to the same extent does not exist?

In corroboration of what had been stated, he added, that the most reliable meteorological observations of the last forty years exhibited a continuous decrease of rainfall, at least in the more southern parts of this island; whilst during the same period the extent of the drainage area had been steadily advancing. The author had no intention of doubting that the benefits of improved drainage were of a high character, and almost equally so those arising from the absence of accumulations of filth near our dwellings. Both were the inevitable results of our advancing civilisation, though each might be made to undergo some wholesome modification. Meanwhile, great as their benefits undoubtedly were, his present object would be attained if he succeeded in calling attention to the vast though hitherto overlooked cost at which they were obtained.

His opinions as to the results of drainage, together with the probable effects of sewer water on the quality of our domestic supply, were first published by the author in 1816. Since that period all his very ample opportunities for practical observation have added certainty to the opinions he had then set forth. It being thus evident that the quantity, as well as the general quality of our water supply was rapidly deteriorating, it struck him that some efficient and cheap mode of effecting its purification would be attended with great public benefit. Accordingly, in 1851, he began to devote himself to the subject, which he had now brought, he trusted, to a successful issue.

At the commencement of his researches, the opinions of all the authorities with regard to the probability of purifying water by artificial means, were summed up at the conclusion of the report drawn up by the Government Commissioners, "On the supply of water to the Metropolis." These gentlemen there said:—"That water cannot be deprived of matter *held in solution* by any practical modification of the process of filtration." This was the state of the subject when entered on by him. His object, from the beginning, was to discover the mode by which nature converted impure coloured surface water into colourless spring water, the operation being apparently one of filtration. His first experiments were made with a view of throwing some light, if possible, on the philosophy of filtration as ordinarily practised, he having some reason to believe the process, when most effective, did not so much depend on mechanical principles as was generally supposed. To determine this point, a long series of very interesting experiments were related, which resulted in showing that properly conducted filtration (*i.e.*, where the gravitating power of the water is not in excess) is dependent on a lateral attractive action exercised by the sand or other media through which the process is performed, this being in addition to the downward action of gravitation. His next object was to discover what bodies in nature exercised this newly-discovered attractive power the best. After trying a number of experiments with various descriptions of rocks and minerals, all of which were described to the section, he found that those containing protoxide of iron (even where it was chemically combined with other substances) effected the filtration of water better than any other. Acting on the idea thus suggested, he found the same oxide, when isolated in the state of "magnetic oxide," not only to free it from turbidity more effectually than an equal thickness of sand, but to effect its decolouration with marvellous rapidity: whilst the other earthy substances entering into the composition of the same rocks, such as silica and alumina, were, in the latter respect, perfectly *inert by themselves*. From this it appeared evident that the protoxide of iron—as magnetic oxide—a substance which enters into

* The British Association, September 17th. Section B.—Chemistry. President—Dr. Lyon Playfair, C.B., F.R.S.

the composition of so many rocks, was one of nature's chief agents of purification. Here the author referred to a series of experiments he had made, showing that the commonly received opinion, that light and air *alone* effected the purification of water, was erroneous. For example, he had put coloured bog water into shallow glass pans, in which it was fully exposed to both these agencies for several weeks—evaporation being compensated by distilled water—but without any change being apparent in its colour. This result, so contrary to what might have been expected *a priori*, led him to refer the natural process to the agency of some other body which probably exercised a catalytic action on the atmospheric oxygen, and thereby induced this gas to combine with the noxious impurities existing in the water. Nor was he mistaken in this surmise, as the results so amply related in the paper, together with the experiments, exhibited to the section, sufficiently attest. A very striking one was made with some bog water, much darker in colour than ordinary porter, which had been procured from the soakings of an Aberdeenshire peat bed. This water was *deprived of colour almost instantaneously* by mere contact with the oxide.

To appreciate this result it is to be remembered that no known agency has been able to effect a similar one before. Since soft water has become so much an object for manufacturing purposes, to effect the decolouration of that of bogs had remained a problem unsolved by chemists. Not only was it now evident that this water could be deprived of all trace of colour, but it was rendered bright, clear, and perfectly free from taste. Several who partook of it pronounced it to be equal in these respects to spring water. Above all, the means by which the change was effected were so exceedingly simple. For example, the coloured water was poured into a glass vessel containing a layer of about five inches of equal parts of coarse sand and a hard ferruginous substance, perfectly magnetic, on which the water issued forth with great rapidity, perfectly colourless.

The action of the oxide, however, was far from being confined to the decolouration of bog water; that experiment had only been brought forward because it could be strikingly exhibited to a public assembly. On the contrary, it equally affected every impurity to which water was subjected—even that of the London sewers had been rendered harmless, and void of all odour and taste by the same means. Besides which, it had resulted from the experiments of Professors Brande and Clark, that soft water treated by the magnetic oxide had no action on lead.

Perhaps the most extraordinary circumstance was, that *the magnetic filtering medium itself suffered no deterioration after any period of operation*. Its province was confined to forcing the oxygen resident in the water into combination with the colouring matter, and thus converting it into carbonic acid, which gas, it need hardly be said, conferred freshness and salubrity on all waters in which it was found. In this result the occult action of catalysis was, for the first time in the history of science, brought at will into useful every-day operation: in explanation of this extraordinary action, the author now entered at some length on the received notions of what was really to be understood by the term "catalysis." He thought it might be satisfactorily shown that the substances inducing this action did so in virtue of their power to alter the molecular arrangement of the bodies they acted upon—as a magnet alters the arrangement of iron filings, even at a distance. He believed he was in a position to show, however, that the phenomenon was strictly identical with electro-polarisation.

In the experiment he had exhibited, there could, he believed, exist no doubt that the magnetic oxide of the filter had the power of attracting oxygen to its surface, and when there this gas necessarily became polarised. Whilst in that state, and *only whilst in that state*, it combined with the organic colouring matter to form a new substance. But the most startling circumstance

he had to relate was, *that the oxygen when in this state of polarity was neither more nor less than ozone*—that fugitive body, of hitherto doubtful origin, which had become so much identified of late with atmospheric salubrity. This novel proposition was illustrated by an equally novel and certainly most convincing experiment, as far as it went. We are unable to give its details farther than by stating that it exhibited a larger amount of oxygen converted instantaneously into ozone by the action of the magnetic oxide, on an alcoholic solution of gum guaiacum, than, perhaps, had ever been witnessed in the same compass before. Though the President evidently had not leant to the author's theory, this unlooked for proof of it elicited his admiration. Mr. Spencer stated, however, that this was only one among many modes he possessed of demonstrating the same fact, viz.:—that ozone was polarised oxygen.

For example, a still stronger proof was cited, viz.:—that the poles of a galvanic battery immersed in the guaiacum solution of alcohol produced ozone in the same manner, *but only at the oxygen pole*. But what he ventured to believe amounted to a confirmation of this view was, that a similar effect was that the battery did *not* produce this effect in a solution with absolute alcohol; water was therefore essential in order that its oxygen might undergo polarity, or in fact, ozonification. Mr. Spencer further stated, that according to his experiments, he had found most natural substances that contained protoxide of iron exercised this power of ozonifying oxygen. Even if this now important oxide was locked up in chemical combination with other bodies, still the power was more or less exercised through the solid covering. The existence of ozone in the atmosphere, therefore, need be no longer a problem. He had proved by his experiments, that air whilst passing over substances of this character became ozonified by contact alone. Henceforth we could account for the salubrity of some winds as compared with others. It would now be evident that the adventitious electricity of thunder storms had but a small share in producing ozone in sufficient quantity for the purposes of nature. But the ferruginous suboxide was not the only one that exercised this important function, as several other metallic sub-oxides which he enumerated partook of the same power, though in less degree. Per-oxide (ordinary rust), on the other hand, or metallic iron, was perfectly inert. He also found that several gum resins exercised a similar power, though in lower degree, over oxygen.

Mr. Spencer now gave an account of a new compound magnetic body which he had succeeded in making to better enable him to carry out the purification of water on a large scale. Though the magnetic oxide he had first obtained from the white carbonate of iron was very effective, yet it had a tendency to be reduced to powder by attrition. He became apprehensive therefore it might ultimately interfere with the rapidity of his filtering operations. This led him to seek some mode of procuring a harder and less friable body. After various experiments he had been successful beyond his anticipations. By very simple means he had formed a magnetic body from the hitherto refractory Cumberland hematite. The new substance consists of iron, oxygen, and carbon—an equivalent of each—its atomic number is therefore 42. Specimens of the new body were exhibited to the section. It appeared very hard, and when polished had a black metallic lustre. It was said to be as incorrodible as gold or platinum, and is highly magnetic. Its purifying powers were stated to be very great. It can be manufactured very cheaply. Mr. Spencer, as its discoverer, had named it proto-carbide of iron.

The President (Dr. Lyon Playfair), at the close of the paper, was sure the section would feel much indebted to Mr. Spencer for the valuable nature of the practical results he had laid before them. Though much struck with the ozone-forming experiment in support of the theory, yet he, the President, hardly felt himself at liberty to give his adhesion fully regarding this view of the na-

ture of ozone. There was another mode of testing the matter, however, which he named, and which, if successful with the magnetic oxide, might carry more conviction to his mind. Mr. Spencer stated that he had not considered the mode named by the President as being so good a test of the presence of ozone as the one he had brought before the section.

At the following meeting of the section, however, this experiment was successfully performed by Mr. Spencer, in the presence of the President, thus affording an additional proof that ozone is only polarised oxygen, and that nature is not confined to one mode for its production.

Copious as this abstract appears, yet we have been obliged to omit several equally interesting topics embraced in the original paper.

COAL-BURNING LOCOMOTIVES.

"D. K. CLARK'S SYSTEM OF COAL-BURNING WITHOUT SMOKE, BY THE METHOD OF STEAM INDUCED AIR-CURRENTS, APPLIED TO THE LOCOMOTIVE ENGINES OF THE GREAT NORTH OF SCOTLAND RAILWAY."

By DANIEL KINNAR CLARK.*

THE substitution of coal, as fuel, for coke in locomotives, is not only felt to be a commercial necessity for the reduction of expenditure, but is also discovered to be perfectly practicable as a mechanical problem in conformity with the conditions laid down by the railway Acts of Parliament that railway engines shall consume their own smoke. The means of doing so, to be adaptable to a locomotive engine, must be simple in design, facile of application to existing locomotive stock, easy to manage, easy to maintain, efficient in promoting the combustion of coal without smoke, keeping up the steam, and saving expense.

These desirable qualifications the writer believes belong to this system of smoke prevention. The whole apparatus is external to the fire-box, and therefore not exposed to heat; and it is controlled in the most perfect manner by a single stop-cock. Air is admitted above the fuel by one or more rows of tubes inserted through the walls of the fire-box, and jets of steam are projected through the air-tubes from nozzles $\frac{1}{16}$ th inch diameter, in small steam pipes, placed outside the fire-box, to increase the quantity and force of the air admitted above the fuel in order to consume the smoke. The jets of steam are used principally when the engine is standing, with the aid of a light draught from a ring-jet in the chimney, to carry off the products of combustion, and they may be shut off when not required. The supply of air through the tube may also be regulated by dampers.

The grate-bars are placed close together, with narrow air spaces, and the ash pan and damper are lightly fitted. The level of the fuel should at all times be below the air-tubes.

This system is working with entire success on the engines of the Great North of Scotland Railway, at Aberdeen. It is also successfully at work daily (amongst other lines) on several of the engines of the North London Railway, where, as a Metropolitan line, the regulations against smoke nuisance are rigidly enforced. It requires a less weight of coal than the engines formerly required of coke for the same duty; and thus saves more than the whole difference in the price of the two fuels.

The locomotive engine has been variously cut up and mangled in order to suit the views of designers for the combustion of coal without smoke. In the plan before the meeting, the original type of engine promulgated by Mr. Stephenson, and at this day universally adopted and unsurpassed, is preserved intact; and the locomotive is thus rendered a complete and perfect machine, and entirely meets the great railway necessity of the day—the perfect combustion of coal in railway engines.

Literature.

Our Engines of War, and How we Got to Make Them. By Capt. JERVIS-WHITE JERVIS, M.P., Royal Artillery. London: Chapman and Hall, 193 Piccadilly. 1859.

As a rapid superficial sketch of the progress made in the production of great and small guns this work has many merits, although its title is undoubtedly too comprehensive and its price too high. The author, known before for his "Manual of Field Operations," his treatise on "The Rifle Musket," and his speeches in Parliament on similar subjects, here gives us only a hundred and eight small pages of matter in very large type, and it is hardly fair, we think, to the reading public to label such a brochure with the broad and sounding title, "Our Engines of War, and How we Got to Make Them," and to charge six or seven shillings (as is done, if we remember rightly) for it. Many of our engines of war are not mentioned at all in the book, and others are passed over very lightly indeed. It is the publishers, however, we presume, rather than the gallant author, who are responsible for the price and title, and it is as a warning to them that we express dissatisfaction on these points. In other respects they have turned the work out of hand very satisfactorily, the type, wood cuts, &c., being of the best kind.

It is due to the author to say that he has made his work very interesting, and has displayed great intelligence in dealing with the various subjects that he has considered. Nor can we refrain from congratulating the public upon the excellent temper and wisdom displayed in the work. There is no jealousy of inventors, no distrust of non-professional men to be found in it; but on the contrary a sound spirit of progress, and a hearty love of improvement manifested throughout. When we remember that the author holds a high military office—that of superintendent of our small arms department—we cannot but hail such evidences of enlightenment with pleasure. Nor is Captain Jervis alone in this respect. From a report which appears in another page it will be seen that Colonel Dixon, who has charge of the works at Enfield, has just been evincing a similar spirit in connection with the Association of Foremen Engineers. We gladly accept such facts as proofs that the old and bad feeling of military exclusiveness, which has cost us so much, is declining, and as omens of its speedy and complete extinction.

The Journal of the Royal Agricultural Society of England. Volume XX., Part I. 1859. London: John Murray, Albemarle-street.

THIS journal is very high-priced, but it is worth all that is charged for it. In the present part we have no less than fourteen articles, some of them of a most valuable nature. Those on the preservation of timber, the application of liquid manure, American methods of economizing labour, and the cultivation of land by steam, deserve the special attention of our readers.

The Drawing-Room Portrait Gallery of Eminent Personages. With Memoirs by the most able Authors. 1859. Second Series. The London Joint Stock Newspaper Company (Limited), 199 Strand; West-end Branch, 123 Regent-street.

WITHOUT the slightest approach to exaggeration it may be said that a book more suitable for a drawing-room table than this does not exist. It contains portraits of at least forty of the most notable persons of the day—statesmen, clergymen, engineers, artists, orators, singers, and so forth; and such portraits as never could be obtained until now at any price, and even now can be obtained nowhere else for twenty times the sum for which they are here supplied. The highest photographic art has guided the highest art of the engraver in their production, and hence we have a result which is both splendid and unique. If the price were many times what it is we should recommend every reader of ours who can afford to put a handsome book on his drawing-room table to put this (and the previous volumelike) there.

The Theory of Compound Interest and Annuities, with Logarithmic Tables. By FREDERICK THOMAN, of the Société Cr dit Mobilier of Paris. London: Lockwood and Co., Stationers'-hall-court. 1859.

THIS is a very ambitious book of its kind, and bears evidence of great research. Fortunately it does not lie within our duty to examine deeply into a financial work, but we may nevertheless say that we have taken the trouble to go through some of M. Thoman's mathematical investigations, and to glance generally through the book, and our impression is that he has produced a very original and valuable work. Professor De Morgan, who speaks with some weight on such a subject, and who has looked into the volume, thinks highly of it.

Mr. Goldsworthy Gurney's Account of the Invention of the Steam-jet, or Blast; and its Application to Steam-boats and Locomotive Engines. London: S. Barclay, Castle-street, Leicester-square. 1859.

MR. GOLDSWORTHY GURNEY here claims for himself an invention which Mr. Smiles has attributed to the late Mr. George Stephenson, and claims it, as we think, with much apparent reason.

THE PROGRESS OF STEAM NAVIGATION AT HULL.

By JAMES OLDRHAM, Esq., Hull, M.I.C.E.*

FOR generations past Hull has been noted for its Greenland and Davis Straits fishery, and for many years this has constituted the chief feature of the port. Within the last two or three years steam has been put into successful requisition to aid the dauntless and hardy mariner in the pursuit of this hazardous calling, and now we have several screw steam-ships employed; and although some of them are fitted with comparatively small power, they have proved to be possessed of great advantage in the service, and in some instances satisfactorily to the owners. We have had two descriptions of steam vessels employed in the fishery; the first, the old wooden sailing ships, which had been engaged in the service for some years, but which were afterwards fitted with screw machinery and auxiliary steam power. The second, iron built ordinary screw steam-vessels; but which proved, I believe, almost a total failure. The material of which they were built, and the want of strength for such a purpose, proving them altogether unfit to contend with the severity of the climate and rough encounters with the bergs and fields of ice, some becoming total wrecks, while others returned bruised and rent, and were with difficulty kept from sinking. A question here arises how far iron ships are calculated to bear the severe frosts of high latitudes, and whether wooden-built vessels, with all their defects, are not the best adapted for encountering such a climate? The screw steam-ship which was first sent from Hull, or any other place, to the fishery as an experiment, was the Diana, timber built, 355 tons and 40 horse-power, high pressure, the property of Messrs. Brown, Atkinson, and Co., of Hull. This vessel had been some time engaged in the fishery as a sailing ship; but her spirited owners, thinking an important advantage could be gained, determined upon the adoption of steam power, and at once had the Diana fitted for the spring of 1857 by Messrs. C. and M. Earle, who put in the engines, and made the screw to lift out in case of need. The experiment fully answering their expectations, Messrs. Brown, Atkinson, and Co., bought the Chase, a fine American built ship of immense strength, and of 558 tons. She was fitted by Messrs. Martin, Samuelson, and Co., with condensing engines of 80-horse power, and despatched

to the fishery in the early part of 1858, and with good results. By the application of steam, ships in this service can now make a voyage first to Greenland, and afterwards to the Davis Straits. In the commencement of this year several ordinary iron screw steamers were despatched to Greenland, viz., the Corkscrew, Gertrude, Emeline, and Labuan, the latter only of this class, which is the property of Messrs. Bailey and Leatham, had any success; but in consequence of her great strength and peculiar form, succeeded in a tolerable way; the others were much damaged, and, as I have already remarked, returned in bad condition. The Labuan is 584 tons burthen and 40-horse power.

The next point of interest connected with the steamships of the port of Hull refers to alterations made in some of the vessels. The Emerald Isle, a paddle timber-built ship of 1835, the property of Messrs. Gee and Co., originally 135½ long, lengthened 35 ft., with a gain of 14 in. draught of water, and an increased capacity for 100 tons dead weight. The Sultana, iron screw steamship of 1855, the property of the same house, originally 150 ft. long, lengthened 30 ft. with a gain of 10 in. draught of water, and an increased capacity of about 100 tons. It is interesting to observe that in both cases we have no diminution of speed through the water, and that both vessels are improved as sea-boats. Daily experience teaches the advantage gained, in almost every point of view, by ships of great comparative length. The iron steamship Lion, of Hull, formerly a paddle-boat 219 ft. long, but now converted into a screw steamer by her owners, Messrs. Brownlow, Lumsden, and Co., under the direction of Mr. Anderson, their engineer, exhibits the great advantage gained by the alteration. Her register tonnage is 690, and the total tonnage 1,014. She was formerly fitted with steeple engines of 350-horse power, and had four boilers, two before and two abaft the engines; but these were substituted for direct action engines of 150-horse power, and two of her old boilers replaced, and by this alteration a clear length of hold in midships of 23 ft. is gained. She required before the conversion 650 tons of coal for a Petersburg voyage, and consumed 80 cwt. to 40 cwt. per hour; but now 850 tons for the voyage, and a consumption of 20 cwt. per hour. By the change of machinery about 130 tons of dead weight is removed from the ship, and she is now able to carry 400 tons more cargo. Her speed is also improved considerably; before the alteration, when drawing on an average 14 ft., the rate was six knots and a-half, but since the change, when drawing even more water, they can steam eight knots. Thus throughout a saving almost in all the departments of the ship, and other advantages, have been effected in this important change. During the last two years many fine steamships have been built in Hull, and others are in process of building for English and foreign service by Messrs Brownlow, Lumsden, and Co.; Messrs. C. and M. Earle, and Messrs. Martin, Samuelson, and Co. The last-named firm are making rapid progress in the building of two large paddle steamships for the Atlantic Royal Mail Steam Navigation Company of the following dimensions, power, &c. :—

	Feet.
Length between the perpendiculars ...	360
Beam moulded ...	40
Depth ...	30
Tonnage, builder's measure ...	2,800
Nominal horse-power ...	800

These ships are to have three decks, and to be fitted fore and aft for passengers. Speed through the water, twenty miles per hour. They will be of immense strength, and their build and form such as to ensure their becoming fine sea-boats.

Since the meeting of the British Association, at Dublin, considerable advance has been made in London and other ports in the application of superheated steam, and, I believe, with great success and satisfaction in the results; Hull, however, before taking a decided step in this important discovery is anxious to see and adopt the best mode of the application of the principle, being assured

* British Association, 1859.

SILVER'S PATENT MARINE AND STATIONARY ENGINE GOVERNORS.

that in every onward movement it is better "to make no more than good speed." Some attention has been paid to the consumption of smoke in the furnaces of our steam-vessels, and with a considerable amount of success. I may here mention the mode of Mr. Ralph Peacock, of New Holland, Hull, for which he has taken out a patent. It consists of a double furnace-door (two views of which are shown in the annexed engraving), the

chamber or space between the inner and outer surfaces being five to six inches in width. The inner plate is perforated very full of small holes, and in the outer plate a revolving ventilator is inserted, which is on the principle of that invented by Dr. Hale, to supply close places with fresh air. The apparatus is in use on board the Helen Macgregor, one of Messrs. Gee and Co's. large sea-going steam-ships, and has given very general satisfaction, for by the report of the chief engineer, Mr. McAndrew, a saving of fuel is effected and the steam better sustained. Another great advantage, as reported by the master, Captain Knowles, derived from this invention is, that on running before the wind, they are never now annoyed and endangered by a dense cloud of smoke in the direction of the ship's course, which, particularly at night time, creates so much risk of collision. This apparatus is also in use on board several other steamers, viz., the Yarrowburgh and Grimshaw, belonging to the Anglo-French Company, the Albert, of Hull, and also a number of river steam-boats. I have great pleasure in noticing also an improvement introduced on board the Queen of Scotland, another ship belonging to Messrs. Gee and Co., for the same object, by the chief engineer, Mr. Smith, and having furnaces of ample capacity, answers the purpose in a most satisfactory manner. Mr. Smith's mode consists simply in keeping a few inches off the front ends of the bars quite clear and clean from side to side of each furnace, thus admitting at the right place a sufficient amount of air. The report of the master, Captain Foster, is very satisfactory; I have witnessed also the effect of this mode on the furnaces of stationary boilers with perfect results.

I have now to refer to the application of Silver's Marine Governor as applied by Mr. John Hamilton, of Glasgow. Several of these ingenious and efficient instruments are now in use on board steam-ships in the port of Hull, giving the highest satisfaction. They are so sensitive in their action, that the slightest pitching motion is at once indicated, and the steam admitted or excluded as the case may be. By the use of this governor (which is illustrated in the annexed engraving), the full power of the engines is in immediate and constant requisition, producing the effect of saving of time, saving of fuel, and preventing of accidents by what is termed racing and otherwise. The ordinary mode, in the absence of the governor, is for the engineer in stormy weather and heavy seas continually to stand at the throttle-valves, or, to save himself this trouble, to throttle the engines, and thereby when the full power of the engines is most required, it is frequently reduced to one-half or less, and consequently there is occasioned a loss of time on the voyage, and the risk of falling on to a lee shore.

SILVER'S PATENT MARINE AND STATIONARY ENGINE GOVERNORS.

Constructed by JOHN HAMILTON, Engineer, Glasgow.

The engraving represents the Momentum Wheel Governor or "Nautical Regulator," as it is usually placed in the engine-room of a steam-ship. It consists of a momentum wheel *A* fixed on the boss of a pinion *B*, which works loosely on the spindle *C*, and gears into the two-toothed sectors *D D*. These two sectors being supported on a crosshead *E*, made fast to and carried with the spindle *C*, work in opposite directions on the pinion *B*; and as they are linked by the rods *FF* to the sliding collar *G*, which receives and works the forked lever *H*, communicate motion to the throttle valve. *MM* are vanes, and *N* is a spiral spring, both of which are adjustable.

The action of the above instrument is as follows:—When the spindle of the governor or "Nautical Regulator" is turned by the engine to which it is attached, the two-toothed sectors, which are carried on the fixed crosshead, being geared into the pinion on the momentum wheel, have the tendency to turn round on this pinion; but as they are linked to the sliding collar, they necessarily pull inwards this collar, and so compress the spiral spring, and this spring reacting on the collar, and consequently on the toothed sectors, serves to turn round the momentum wheel, while the vanes on the momentum wheel balance the action of this spring by the resistance the atmosphere offers to their progress through it. As the leverage action of the toothed sectors upon the momentum wheel pinion increases as the spring

becomes distended, and *vice versa*, it will be seen that the reaction of the spring in propelling the momentum wheel will at all times be uniform, and as much only is required as will carry round the momentum wheel with its vanes at its proper speed, and overcome the friction of working the throttle valve and throttle valve connections. When the momentum wheel is in motion, it will rotate with the engine to which it is attached at a velocity proportioned to that at which it is fixed by the connecting gear; and while the engine from the usual causes may attempt to vary this velocity, it cannot affect the momentum wheel, but leaves it free to act upon the allding collar, and consequently upon the throttle valve—at one time closing the throttle valve by its action in resisting any increase of velocity, and at another time opening the throttle valve by its action in resisting any decrease of velocity on the part of the engine. It will now be evident that the power of such a governor or regulator must be very great indeed, having for its agent a momentum wheel which may be increased to any dimensions, and from the powerful resisting tendency of such wheel, it necessarily follows that its sensitiveness of action must also be very great, and in exact proportion to the tendency of the engine to vary its speed; and the engine itself being the direct prime mover of the throttle valve, it also follows that the inert power of the momentum wheel increases its resistance exactly in proportion to the rapidity with which the engine varies its speed. Hence, a momentum wheel of two feet eight inches diameter, and two inches periphery, running at a speed of 180 revolutions per minute, is found to be sufficient to work with promptness and ease the largest throttle valve, and to equal the power of several men. Unlike the ordinary forms of governors, it is entirely unaffected by changes of position, and therefore perfectly adapted for marine and portable, as well as stationary steam-engines.

The continental papers state that preparations are being made for an Agricultural Exhibition in St. Petersburg in September, 1860.

During the past week no fewer than 40 total wrecks have been posted on the books at Lloyd's. Among the more calamitous were the destruction by fire of the ship *Schah Johan*. She was bound from Calcutta to the West Indies, and had on board 300 coolie emigrants. For four days every effort was made to save the ship and the unhappy creatures on board, and ultimately three rafts, crowded by 300 souls, were set adrift, and have never since been heard of. The masters, officers, and crew, about 60, were picked up in a very distressed condition, five days after, by the ship *Vasco de Gama*. There are, in addition, several missing vessels, respecting which the most painful forebodings are entertained.

DENNY'S LIFE BUOY.

FIG. 1.

FIG. 2.

DENNY, Clerk of H. M. ship *Britannia*, at South, has invented a new description of buoy, which appears to possess some decided advantages over the ordinary buoy used in the

Instead of the two hollow copper spheres used by a cross-bar as used in the old life buoy, Mr. Denny adopts an annular float, within the balance bar works by a very simple and easy arrangement, the whole of which affords facilities for the immersed person to get hold of the buoy, and, by saving exertion, prevents exhaustion of strength, and enables the person to sustain himself longer as otherwise could do.

Denny's plan has been examined by experienced naval officers, who have expressed themselves well pleased with it, and it doubtless be brought to the notice of the public.

Following is a description of Mr. Denny's buoy by the inventor:—His invention consists of a hollow copper sphere with a suspended stanchion in the centre to hold the light. Two indentations, one on the top and the other on the under surface of the sphere, and opposite each other, allow this stanchion to move in a perfectly horizontal direction to the centre of the ring when suspended; on being let go, it becomes perpendicular, and is locked in that position by a catch. It is nearly impossible to move this buoy. Hollow copper balls suspended on the same guides or on others at the ship's stern, connected with the buoy itself by floated lines, give an additional chance of safety to a sinking person, as, even if ten or twelve feet from the buoy, he may manage to draw it to him by their aid. It may either be fired in the usual way, the present guides, slip, and friction hammer being retained; or a friction hammer may be used, firing the fuze by the weight of the buoy on being let go. Kisbee's reed life buoy may be fitted on this principle with little alteration. W. B. DENNY.

EXPLANATION OF DIAGRAMS.—Fig. 1 shows the buoy at the ship's stern; Fig. 2 shows it at the ship's bow. A, hollow copper buoy; B, stanchion holding light; C, weight to balance light; D, to secure stanchion in a perpendicular position; E, plate for the fuze and light; F, copper or cork balls; G, guide rods; H, for guide rods; I, lines floated with attaching balls to buoy.

TAYLOR'S PATENT STEAM ELEPHANT.

THE subject of steam traction on common macadamised roads and over soft ground, is now engaging the attention of the public. Taylor's patent steam elephant, a side elevation of which we here give, is a very compact and well-arranged machine for the purpose. It consists of a tubular boiler 4 ft. 8 in. long, with the fire placed in a flue, and the flame returns through a number of tubes to the chimney, which is situated at the same end as the fire-door; by thus shortening the boiler there is no fear of any of the tubes becoming uncovered during the course of the engines up steep inclines. The furnace is also adapted to the burning of wood, and is fitted with a simple smoke-consuming apparatus. The funnel passes through the dome of the boiler, so as to superheat the steam, and is provided with an efficient spark catcher.

It will be seen on reference to the engraving, both engineman and steerer stand in front of the engine, which is without doubt their proper position, and both fuel and water sufficient for a distance (with a load) of about fifteen miles, are stowed away in a very compact manner. The driving cylinders are placed upright at the end of the boiler, and drive the wheels, which are situated at the tail of the engine, and which gear into the main driving wheels, which make about 14 revolutions, while the engines are working 280 revolutions per minute. The chief part of the weight of the machine is over these wheels, which are 6 ft. in diameter, with broad peripheries, so as to give a good hold upon the ground; they are also so arranged that they will adjust themselves to work at different speeds when rounding a corner. The total weight of the machine, including fuel and water, is seven tons, and its power that of six horses; there is also no difficulty in checking its progress when going down an incline.

The utility of this engine is not confined to traction purposes, as by means of clutches the engine can be disconnected from the driving gear, and can then be used for pumping, hoisting, or driving machinery; the whole machine rests on springs, and the condensed water from the cylinders, safety valves, &c., is used for heating the feed-water, so as to economise fuel as much as possible.

On reference to the engraving it will be seen that A shows position of boiler; B, the gearing; C, the driving-wheel; D, steering apparatus, and E the fuel box. As to the practical working of these engines, the results have proved most satisfactory. The amount of fuel consumed when in full work is 70 lbs., and of water 28 gallons, per hour. The speed of the machine with a load is equal to about three miles per hour, although

alone it will run six easily; so, taking the other expenses, including 20 per cent. per annum for depreciation of the value of the machine, we have the following result, viz., that Taylor's engine will draw a weight of 16 tons a distance of 36 miles in the 12 hours at a cost of 2s. per ton; this is two-thirds of a penny per ton per mile. It would be waste of time to enlarge upon the advantages of this mode of traction over that by animal power. It is now an established fact, and the application of the system becomes a mere matter of economical mechanical arrangement and improvement from time to time.

TAYLOR AND GRIMSHAW'S PNEUMATIC APPARATUS.

THE following has been submitted to us for publication:—"There may be seen at the Crystal Palace an instrument, recently patented by Messrs. Taylor and Grimshaw, of Southampton, which is calculated in a very high degree to add to our comfort and safety; it has

a variety of action; perhaps its most prominent feature is its fire alarm apparatus. As such, it is capable of becoming a sideboard or bed-room ornament; its action is perfectly simple and invariable, either in a dwelling or factory, or in the hold of a ship. It may be set to any degree of temperature, when that is exceeded it indicates the fact; first, silently, then by its loud ringing alarm; or, if required, it discharges a powder cell

with the report of a pistol or nine-pounder, as may be required, either to alarm the inmates of a house or the neighbours of an uninhabited mill, church, or other edifice. A simple application of the hands to the sides of the machine at once sets the indicator in motion, and explains its action. A second form of its application is a ventilator. If tested in the same manner, it will open a ventilator, which will close on the removal of the hands. For common purposes, it may be set to any required temperature as may be needed for your chamber, conservatory, or barrack-room. When the required temperature be exceeded, the

lator opens, and so remains until the desired temperature be regained. As indicative of heat, it acts in the same manner, and can in the same way be tested for sea purposes: a long tube rising from the hold of a ship, or wherever required, having at its summit on deck a simple dial, which shows at all times the heat below, giving timely warning, and averting the sad calamity of a ship on fire at sea. It is also a heat regulator, working a damper by which air is admitted more freely, or excluded from the fire. It is susceptible of a variety of other applications. The above are all easily tested and understood. The principle upon which this variety of useful application is based is the enclosure of common air within an airtight metal cylinder, having on its upper side a firmly-fixed diaphragm of india-rubber, upon which rests the spring which works the indicator. The enclosed air expands or contracts as the surrounding air becomes hotter or colder, acting in its expansion or compression on a spring which causes the indicator to show upon the dial the temperature obtained, and giving its loud warning when the dangerous degree has been attained. The apparatus in question has neither wheels nor arrangement capable of getting out of repair: no mercury or other fluid than air is used; and it would be rather difficult, without some trouble, to cause it to work inaccurately."

The above account proceeds from the inventors, and may be taken as their view of an apparatus which has been favourably spoken of in the city articles of most of our newspapers during the past week, and in other places. That our readers may be able to judge for themselves of the merits of Messrs. Taylor and Grimshaw's invention we have had the annexed engraving of it, as arranged for an alarm, prepared. *A* is the diaphragm, *B* a rod which rises and falls with it, and which has a threaded portion *C* working into a wheel on the axle of the pointer *D*. The pointer *D* indicates the temperature on the graduated arc *E*, and above this is a second arc which turns upon, and may be clamped to, the axle of the pointer. Above the second arc is a disc, bell, and hammer, so arranged and connected with a weight (not shown) that by suitably adjusting the second arc the hammer may be released and caused to beat upon the bell when any given temperature is attained.

ARTESIAN WELL AT WOLVERHAMPTON: "ON AN ARTESIAN WELL IN THE NEW RED SANDSTONE AT THE WOLVERHAMPTON WATERWORKS."

By J. F. BATEMAN, Esq*.

THE town of Wolverhampton has been up to a recent period supplied with water produced by two deep shafts—one sunk about 300 feet deep into the lower New Red or Permian measures, and the other to a somewhat similar depth in the New Red Sandstone proper. From both of these wells a large quantity of water was anticipated by the engineers who advised their construction, but their yield is under 200,000 gallons a day each, the water being pumped in one case from a depth of above 180 feet, and in the other 246 feet.

The quantity thus yielded being insufficient for the supply of the district, new works have been constructed which I have just completed for bringing water from the river Worth at Corford Bridge, about nine miles from Wolverhampton and three from Shiffnall, in the county of Salop.

The works are constructed for the supply of 2,000,000 gallons per day, and the water has to be forced to a height of 500 feet for the supply of the town.

The river Worth at the place at which the pumping works are constructed is not more than 40 or 50 feet above the Severn, which it joins at Bridgmouth, about eight or 10 miles distant. It may, therefore, be considered to be at the bottom of a basin, little elevated above the sea. From the character of the surrounding hills and the inclination of the beds of the New Red Sandstone, it appears to me very likely that, although the wells

which had previously been sunk on the high plateau of Wolverhampton had proved comparative failures, a considerable quantity of water might be found in the sandstone at Corford Bridge, and that possibly some might rise to the surface and flow as an artesian well.

I therefore obtained the sanction of the directors of the company to sink a bore hole for the purpose of ascertaining the fact.

In some parts of the country, as in Cheshire and Lancashire on the shores of the Mersey, the New Red Sandstone is very clearly divided into four distinct portions, consisting of an upper hard mass about 300 or 400 feet thick, a soft mass about the same thickness, a second hard mass, and a lower soft mass, all of pretty much the same thickness. In the neighbourhood of Wolverhampton and Shiffnall, these distinctions are not so clearly exhibited, but I had reason to believe, from the portion of the works, that a bore hole of about 200 feet in depth would pierce the hard rock on which they were situated and reach the soft rock beneath.

The bore hole was commenced twelve inches in diameter, and continued at that size for seventy feet in depth, when it was diminished to seven inches, and continued for 190 feet, one being a total depth from the surface of 260 feet.

The first water was met with at a depth of 25 feet 4 inches, and from that time it rose to the surface and flowed over an artesian spring, increasing in quantity as the depth increased, till the boring was discontinued, at which time it amounted to about 210,000 gallons per day.

The following table will show the manner in which the water increased:—

Depth below surface.	Yield in 24 hours.	Depth below surface.	Yield in 24 hours.
Ft. in.	Galls.	Ft. in.	Galls.
25 4 ...	2,880	110 0 ...	37,023
29 4 ...	3,553	123 0 ...	43,200
37 0 ...	3,002	112 4 ...	61,800
45 0 ...	5,190	153 2 ...	74,055
63 3 ...	9,257	109 0 ...	86,400
78 6 ...	18,514	178 11 ...	120,000
89 0 ...	21,000	185 0 ...	130,800
95 0 ...	23,503	211 1 ...	163,200
101 0 ...	25,020	221 7 ...	183,000
111 2 ...	32,430	239 0 ...	200,830

Throughout the whole depth of boring the rock varied little in character. It was nearly all hard rock. Sometimes very hard, with occasional beds of softer stone. For the last forty feet or so, the soft beds were thicker, but otherwise there was little change from top to bottom.

The greatest increase of water took place at 214 feet and 227 in depth, at each of which depths there was an increase of 20,000 gallons per day.

The soft rock I anticipated was not met with at the depth I expected, but sufficient was done to prove the abundance of water. A large bore hole, which would permit the descent of a larger column of water, would materially increase the produce as an artesian well, while a shaft sunk thirty feet or forty feet deep, and exhausted to that depth by pumping, would yield a very considerable quantity. As the whole rock is charged with water to the level of the river which forms its natural outlet, and as the boring shows that the lower beds receive their supplies from distant sources, the supply to be obtained may reasonably be expected to be inexhaustible within the limits of that which is due to the percolation of the rain upon the collecting area.

On Saturday the great bell of Westminster sounded for the last time, and while in the very act of striking Big Ben became dumb for ever. The bell is even more hopelessly cracked than its ill-fated predecessor. Such a weary deal has to be done before Ben's mutilated fragments find their way to the melting pot, and still more before the renovated mass is again restored to its lofty dwelling, that, even taking a sanguine view of things, we think, with the *Times*, that at the least a clear twelve months must elapse before the voice of the great bell can again be heard booming over the great province of houses in which it is to regulate the laws of time. The cause of its destruction is explained by Mr. Loseby on another page.

ON A SAFETY CAGE FOR MINERS.

By ROBERT ATTOUN*.

THE object of the present invention is to save the lives of miners who may happen to be in the cage at a time when the rope to which it is attached gives way.

It fortunately happens that almost every shaft is provided with a pair of strong wooden rods, called guide-rods, which extend from top to bottom. These are placed on opposite sides of the shaft with the cage between them. The latter is furnished with iron shoes or slides at top and bottom, which loosely embrace the guide-rods and constrain it to keep one path in ascending and descending.

To cause the cage, on the failure of the winding tackle, to cling to these guide-rods is the object sought in all safety cages.

My plan for effecting this is a mere adaptation of an instrument well known to miners—the key or wrench used for raising and lowering the boring-rods. This little instrument has never been known to lose its hold. It supports 100 fathoms of rods with the same tenacity that it does ten. Indeed, the greater the weight it is required to hold, the firmer is the gripe. It therefore is admirably calculated to support the cage, which, in addition to its own weight and load, may have to bear the weight of some hundred fathoms of rope precipitated on it from above.

To adapt this instrument to the cage, a slight modification of the upper shoes and slides is all that is necessary. These shoes or slides are, as usual, two in number, and placed on the opposite sides of the cage and in opposite directions. Each of them has a single bolt or stud, by which it is attached to the cage, and around which it turns; a long arm, to the extremity of which the winding chain is attached; a stop, which prevents the arm from being pulled above the horizontal line; and a spring, which lowers it when the winding chain is slack.

From this description it is easily seen that in the event of the rope or gearing giving way, the springs so tilt the shoes or slides that they immediately seize hold of the guide-rods, in the same manner as the boring key in the hands of a miner lays hold of the boring rods, and with the same tenacity of gripe; and although the rope should come down on the top of the cage, the only effect would be to cause the shoes to dig deeper into the guide-rods, and thus to make the hold more secure.

STRAIGHTENING A CHIMNEY STALK.

THE operations for restoring the colossal chimney at Port Dundas to a perpendicular and safe position are now successfully completed. This was accomplished by sawing several of the mortar beds between the courses on the side from which the chimney leaned, thereby allowing it to come back by its own weight, without the application of any external force. Only one draft was cut at a time, to guard against any shock which might have endangered the stability of the building, and by keeping the saws wet a bed of mortar was prepared for the superincumbent weight to settle down upon. 12 cuts were made in this manner, on different parts of the structure, which generally set before the saws had passed through half of the circumference, particularly in those made nearest the ground, where the weight was greatest. We have to congratulate the proprietor and Mr. Duncan Macfarlane, architect, by whose advice this method was adopted, on the success of their undertaking. The principal dimensions of the chimney are:—Total height, 463 feet; from surface to top of cope, 454 feet; outside diameter at foundation, 50 feet; at surface, 34 feet; at cope, 14 feet. According to calculations made by Professor Rankine, the building, independent of the adhesion of mortar, is capable of sustaining with safety a lateral pressure of 66 lbs. per superficial foot at its weakest point, being 11 lbs. more than the force of the greatest storm registered in this country.—*North British Daily Mail*.

ON THE NOMENCLATURE OF METRICAL MEASURES OF LENGTH.

By G. JOHNSTONE STONEY, M.A., M.R.S.A.*

In this paper many circumstances were pointed out which render the French names of decimetre, centimetre, and millimetre, unsuited to this country. They are foreign to the genius of our language, which delights in short pithy words; the information they convey is useless, as the fact that each measure is one-tenth of that above it is one of that class which it is impossible to forget, and they fail in several common requisites of a good nomenclature.

Names of measures for ordinary use should, if possible, be monosyllables; for the convenience of reference they should begin with different initial letters; they should so wholly differ in sound that even when imperfectly pronounced they could not be mistaken for one another; and they should convey some information which would facilitate the use of the measures by those who are unfamiliar with them.

To combine these advantages it was suggested that *hand* or *handbreadth* should be used as the English equivalent for decimetre; *nail* or *nail-breadth* for centimetre; and *line* for millimetre. The author stated that he had had abundant experience of the assistance afforded to beginners by these names, from their promptly suggesting, without any mental effort, the *absolute length* of each measure.

Attention was also directed to the importance of giving a distinct name to the tenth part of the line or millimetre, in order to discourage the use of binary subdivisions. *Mite* was suggested as a suitable name.

The paper closed by urging that the use of foot-rules graduated along one side to metrical measures should in every possible way be encouraged.

MR. LOSEBY ON BIG BEN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE." October 1.

GENTLEMEN,—The great bell of the clock-tower has again been broken. This has resulted from the use of a much larger hammer, for the weight of the bell, than the usual proportion, and the employment of so great a quantity of tin in the composition as to render it unusually brittle.

For this disaster, as well as for the former, Mr. Denison is entirely responsible.

After the confirmation of the views concerning the enormously disproportionate force of the first hammer, which I published in the *MECHANICS' MAGAZINE* months before the first bell was broken, others have shared the opinion that the second bell would meet the same fate as the first. I may particularly mention Mr. Quarm as having expressed his conviction to that effect, and Mr. James as having proved the extreme brittleness of the metal by breaking three small bells, made from the same composition, with very light blows, in Mr. Denison's presence, at Messrs. Mears's foundry.

Surely Mr. Denison's career as bell-founder and clock-maker, under the sanction of Government, will now come to an end; for it has resulted in more failures, and brought greater discredit on the arts of bell-founding and clock-making than we otherwise find recorded in this country during the last century. Yours, &c.,

R. T. LOSEBY.

October 4.

GENTLEMEN,—Since the above letter was written, an account has been published in which the cause of the fracture is ascribed to the bell having been tightly screwed up to the frame, without the possibility of motion when it was struck. This is erroneous, as I noticed the bell whilst sounding the hour on Wednesday last, and observed it to recede at least three-quarters of an inch from one of the blows; and it must, moreover, be remembered that where clock hammers are used on *swinging* bells they are placed at a right angle to the plane in which the bell swings, and that they cannot

* Abstract of British Association Paper, 1856.

therefore recede from the blow beyond the small quantity which the beam and other parts bend; and which altogether does not generally amount to one quarter the space through which the present bell receded. At the same time there is no doubt but that the larger the bell, the greater distance it should be allowed to play, not only to guard against fracture, but to permit the hammer to follow it up and remain in contact long enough to overcome the inertia of the mass, and set the entire bell in sonorous vibration.

In order to carry out these views Mr. Quarm proposed that the bell should be suspended from a ball and socket joint to allow it to yield and gradually absorb the force of the blow; but the plan was not adopted. My own plan for the same purpose is as follows:—The bell to be suspended so that it can oscillate freely in the plane of the blow, but not in any other, and it will then become a pendulum swinging in tolerably uniform intervals; then let the time of its oscillation be ascertained, and the interval between the blows of the hammer be so regulated that the bell should be making one of its return vibrations as the hammer descends to meet it. Each blow would then be made to neutralise the motion caused by the last one; and all accumulating or uncertain motion be prevented, and the advantages would be secured of the bell hanging perfectly free to accommodate itself to the force of the blow, without the recoil spring having to keep the hammer at a great distance from the bell. The strain on the mountings and frame would also be considerably reduced. Yours, &c.,

R. T. LOSEBY.

SPILL'S MILL BANDS.

THESE bands are now being applied to the Government works at the Royal Arsenal, Woolwich, and at the Ordnance Small Arms Department at Enfield, to drive machinery at both these important official establishments. Besides the tests to which they have been, and are continued to be submitted at the Government contract works on Stepney Green, several of our most eminent engineers have put the material privately to various extreme tests, and many very interesting conclusions have resulted. Not the least of these is its perfect adaptability to paper mills, where from their thorough uniformity of thickness throughout, great smoothness of motion is secured, and the breakage of the paper or disintegration of the flocking of the fibre is entirely got rid of. This will be shown to those acquainted with the peculiar necessities of the case and the singular evenness of the patent band. The same reason likewise gives it singular advantages in flour mills where "lifts" are employed. Another peculiarity in the economy of these bands is worthy of notice; although one surface may wear in process of time, the layer may be altogether removed, and thus the band is only decreased in thickness, but not in comparative utility, as with its regular diminution of thickness it merely sinks to a lower application of power; for instance, say a six-ply band has been in use for months upon a 30-horse power engine, the necessity of the removal of one ply may or may not make it necessary to place it upon a 20-horse power.

ASSOCIATION OF FOREMEN ENGINEERS.

AT the ordinary monthly meeting of the Association of Foremen Engineers, held at 35 St. Swithin's-lane, City, on Saturday last, Mr. Hayes continued his series of papers illustrative of the manufacture of the rifle. The portion of the weapon which was more particularly alluded to on this occasion was the bayonet—the strength, lightness, and beauty of which, as a mechanical piece of work, are remarkable. The various processes connected with the completion of the warlike ffitment were described carefully by the reader of the paper, but his explanations were rendered much more plain from the fact that a perfect and exquisitely finished Enfield rifle lay on the table for the inspection of the members. Space will not admit of our going, at present, fully into detail with regard to the manipulations of the rifle-bayonet, but the number of these is considerable—more, indeed, by

far than a casual glance at the instrument of death would lead one to suppose. Suffice it to say that Mr. Hayes' very lucid account of it met with the cordial approval of his brother foreman, who, after the discussion, and at the instance of Mr. Briggs, accorded him a vote of thanks for his pains.

Mr. J. Newton, who filled the chair on this occasion, took the opportunity of saying towards the close of the proceedings that he had a very gratifying duty to perform, and it was that of proposing also a vote of thanks. The beautifully-made implement of war which lay on their table had been in the kindest manner possible sent for their inspection by Col. W. M. Dixon, R.A., Superintendent of the small-arms factory at Enfield Lock, and who had on several previous occasions shown the utmost anxiety to forward the interests of the Association of Foremen Engineers, and it would ill become them not to acknowledge his disinterested friendship. Mr. Newton then formally proposed that "the thanks of the meeting be given to Colonel Dixon for having forwarded the rifle-musket for their instruction that evening, and for his general goodwill towards the Society." Mr. Keyte seconded this "with great pleasure," and it being carried by acclamation, Mr. Hayes was commissioned by the chairman to convey an intimation of the vote to the Colonel.

Shortly after this the meeting came to an end.

Our Weekly Gossip.

WE find that the remarks attributed to Mr. Neilson in our last week's article upon the hot-blast iron question were made by Mr. Marten, of Wolverhampton, at a meeting at which Mr. Neilson spoke. Mr. Neilson's observations preceded those of Mr. Marton, and the transition from the speech of one to that of the other, being marked only by the use of capital letters in the name of the latter gentleman, was not observed by us.

Under the provisions of the Mercantile Marine Act, the Great Eastern would not be permitted to carry passengers on her trial trip, and the directors have just discovered that they would be liable to heavy penalties if they did so before receiving the certificate of the Marine Department of the Board of Trade. We are informed on good authority that Mr. Scott Russell will take charge of the paddle-engines and boilers on the next occasion, and that Messrs. Boulton and Watt will in like manner hold themselves responsible for the screw engines and boilers, both finding their own officers and men. We hope to be on our way to Weymouth, for the purpose of being present at the trial trip, before this Number reaches our readers.

A course of six lectures on Social Science, embracing all the relations between labour and capital, is about to be delivered by Mr. Wm. Ellis, under the authority of the Committee of Council on Education, at the South Kensington Museum. These lectures are particularly addressed to school teachers, but the general public will be admitted as far as there may be room in the theatre. The first will be given on Tuesday, 11th Oct., and they will be continued on each succeeding Tuesday.

The *Illustrated News of the World*, of Saturday last, has the following:—"In the *Times*' graphic description of the opening of the Swansea docks the other day, there was a slight but interesting notice of the delicate potency of Sir William Armstrong's hydraulic apparatus, evidenced in the case with which the presiding young lady of the occasion made huge gates and other heavy masses move by a trifling pressure of her hand. Sir William Armstrong's fame, with the general public, rests upon his celebrated gun; but his most intimate friends and admirers always maintain that eventually his application of vastly improved hydraulic power will be of paramount value and importance, and will yield results second only in importance to those of the steam-engine. Sir William's gun experiments date only from 1854, but his hydraulic inventions are much older. He was born in 1810, and at the age of twenty-eight, when still a lawyer, he wrote to the *MECHANICS' MAGAZINE* on the improved application of water-power, then (and, perhaps, now) his favourite subject. Some of our readers may remember the steam-electrical machine which he exhibited at the Polytechnic Institution, and which attracted such very general attention. If all we hear be true, perhaps some Great Eastern of the future may be worked by an improved hydraulic engine of Sir William's. What a triumph of mechanical skill; no coals, no over-heating, little or no dread of fire or of explosion." We need hardly say we do not share in the anticipations of the last two sentences.

The following report on the state of the Thames is from Mr. Bazalgette, the engineer of the Board of Works:—"I beg to report that in consequence of the decrease in the temperature the liming operations were maintained during the daytime only from the 12th of August to the 3rd instant, at which latter date, upon the advice of Mr. Miller, the operations were discontinued. The total quantity of disinfectant agents used during the past season has been about 4,381 tons of chalk lime, 478 tons of chloride of lime, and 50 tons of carbonic acid, at a cost of £17,733.

The following information respecting the Royal Gardens at Kew, furnished by W. J. Hooker, Esq., the Director of them, will be of value to many readers:—"The Botanic Garden constitutes one portion of the Royal grounds of Kew. It comprises 75 acres, includes all the plant-houses, and is separated by a light wire fence from the pleasure-grounds. It is accessible to the public every day (Good Friday alone excepted), from 1 o'clock (2 o'clock on Sundays) till sunset, throughout the year. The pleasure-ground is an adjacent part of the domain—a richly-wooded park, bordered on one side by the Thames, consisting of nearly 250 acres, and now, by recent planting, constituting a noble arboretum of all trees and shrubs that will bear our favoured climate, and intersected with extensive and well-kept walks. A lake of five acres, with islands, is forming, and a new conservatory, or winter garden, of unprecedented size, for tender trees and shrubs (rhododendrons, camellias, &c.), is sanctioned and provided for by the Crown. This building will be erected by Mr. Decimus Burton, the architect of the palm-house, and is to be commenced forthwith. This fine piece of ground, possessing no particular attraction in winter, nor much shelter in bad weather, has not hitherto warranted the cost of gate-keepers, &c., necessary for the admission of visitors at that season. The expressed wish of the public has, however, been considered by the First Commissioner of Works, and Mr. Hooker has been instructed by that gentleman to keep open the pleasure grounds during the present month of October. There are three entrances to the pleasure grounds from the public road; first, by the Brentford-gate; second and third, by the Lion and Unicorn gates on the Richmond-road. The entrance to the Botanic Garden is open daily, and during the period when the public have access to the pleasure-grounds there are communications by four gates between these grounds and the Botanic Garden.

The *Times*' Paris Correspondent still contends that the French Government is most active in respect to its fleets and naval defences. He tells us that in the *Moniteur de la Flotte*, the semi-official organ of the naval interests of France, the following passages appear:—"There has just been finished at L'Orient the Couronne, ship-of-the-line of the second class. This vessel is one of 10 now in construction, and which are to be finished within a year from this time." The *Armoricain* of Brest says:—"Our port has just put upon the stocks the ship-of-the-line Magenta, the construction of which has been ordered by the Emperor, and the plans of which have been made by M. Dupuy de Lôme, Director of Matériel at the Ministry of Marine, after the Emperor's own ideas. This vessel will be blind (steel-plated). Its length will be, it is said, 100 metres (328 English feet), including the large iron spur which it will bear in its front. It will be a pattern vessel of a new model." Letters from the provinces confirm, he says, what he recently wrote respecting the general armament of the French ports and coasts. "I am assured that on the Provençal coast the Government has purchased pieces of land at very high prices, for the purpose of erecting fortifications upon them." The *Echo Agricole* has the following paragraph:—"The War Department has just sent to Cherbourg, St. Malo, and other points of our coast the plates which are to be used in the establishment of revolving batteries. These plates are broader and stronger than those employed on railways to change the direction of locomotives and waggons; like these last they are composed of various pieces, which fit into each other when mounted on the wooden framework which puts them in motion. Thus a cannon placed on these new platforms may be turned in an instant in any direction, at the will of the gunner." A letter from Boulogne says that a floating battery is about to be constructed there, with a double tier of guns. It is to be iron-plated, without masts or sails, navigated by steam, and armed with rifled guns.

The prospectus has been issued of the East India Steam Navigation Company, with a capital of £120,000, in £5 shares. The object is to send out steamers to navigate the inland rivers of India—the principal existing company engaged in that trade having for years past realized great profits.

NOTICES.

We have to acknowledge the receipt of numerous letters, papers, periodicals, and other communications which we cannot here refer to in detail. Many of these will appear at an early opportunity—some of them next week—but are unavoidably deferred for the present.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 1s. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 1d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

CORRESPONDENTS' QUERY.

GENTLEMEN,—Will some of your readers favour me with the power of metals to resist a twisting strain, when in the form of a solid cylinder, and when in the form of a hollow cylinder—the quantity of metal in each being equal? A MECHANIC.

October 4th, 1859.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment:—

STEAM ENGINES, &c., 630.
BOILERS AND THEIR FURNACES, &c., 576, 588.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 591, 592, 596.
SHIPS AND BOATS, including their fittings, 553, 559, 578, 583, 615, 616, 623, 632.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 581, 584, 610, 626, 628.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 565, 605.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 554, 558, 560, 567, 574, 575, 579, 582, 586, 593, 597, 598, 600, 627.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 563.
LIGHTING, HEATING, AND VENTILATING, 509, 577, 580, 606, 609.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 555, 566, 562, 614, 618.
METALS, including apparatus for their manufacture, 594, 610.
CHEMISTRY AND PHOTOGRAPHY, 589.
ELECTRICAL APPARATUS, 607.
WARFARE, 564, 566, 573, 611, 620, 624, 625.
LITTER PRESS PRINTING &c., *None*.
MISCELLANEOUS, 532, 551, 557, 559, 561, 568, 570, 571, 572, 585, 587, 590, 595, 599, 601, 602, 603, 608, 609, 612, 613, 617, 621, 622, 629, 631.

552. F. J. JONES. "An improvement in buckles and clasps." Dated March 2, 1859.

This consists in the use of a compass as an ornament in buckles and clasps. *Patent abandoned.*

553. J. W. HARKER and J. K. FIELD. "Improvements in coating the bottoms of iron and other ships and vessels." Dated March 2, 1859.

This consists, 1, in applying a comparatively insoluble soap, prepared by boiling an oxide of lead with fat or oil, to the coating of the bottoms of iron and other ships, such application being made hot. 2, In applying the substances produced by the action of deutoxide of nitrogen in fatty and oily matters to the coating of the bottoms of ships, such application being made hot. *Patent completed.*

554. E. ROCHE. "Improvements in the manufacture of paper suitable for forming cigarettes and for other purposes, and also improvements in the manufacture of cigars." Dated March 2, 1859.

The patentee claims the application of the ribs of the leaves, and the leaves and the juice of tobacco, to the manufacture of paper, suitable for forming cigarettes, &c., and also moulding the paste obtained from these matters into cigars. *Patent completed.*

555. C. HILL. "An improved construction of stay fastening." Dated March 2, 1859.

This relates to a construction of stay fastening, which permits of the stay being slackened or tightened as required without interfering with the lacing. This result is attained by forming the steel bulk with slots for the reception of a hook. *Patent abandoned.*

556. W. E. NEWTON. "Improvements in the construction of barometers, or instruments to indicate pressure." (A communication.) Dated March 2, 1859.

The object here is to produce a portable barometer in a cheap form. One of the essential features of the instrument is a box made of metal, glass, caoutchouc, or other material which is sufficiently elastic by its nature, or by the form of the ox, to admit of the atmospheric pressure compressing or acting upon it naturally. *Patent completed.*

557. J. H. JOHNSON. "Improvements in the construction of grease boxes, and bearings generally." (A communication.) Dated March 2, 1859.

The objects here are efficiently lubricating the working parts of the axle, &c., preventing the escape of lubricating material, and avoiding the entrance of dust or other foreign matters into the bearings. We cannot give space to the details of the invention. *Patent completed.*

558. J. KERSHAU. "Improvements in means or apparatus employed in weaving." Dated March 2, 1859.

This consists, 1, in means for regulating the delivery of the warp as drawn from the warp beam or roller. 2, In means for effecting a uniform winding on of the work on to the work-roller beam. *Patent completed.*

559. J. NEWCOMB and J. G. LOVELL. "Improvements in obtaining and applying motive power, especially adapted, amongst other purposes, to the propelling of ships and vessels." Dated March 2, 1859.

This invention is not clearly described apart from the drawings. *Patent completed.*

560. H. BROWNE. "Improvements in machinery for cutting and finishing the surfaces of wood and other fabrics." Dated March 2, 1859.

Here the lengths of cloth, &c., are passed over a metallic bar, the upper surface of which is indented, turreted, or castellated in divisions of the required width, the end which first passes over being secured to a revolving roller. On the fabric to be finished is placed immediately above the castellated bar, a circular revolving knife which presses the cloth between it and the bar before mentioned, the consequence being that the only parts of the fabric upon which the knife operates are those which touch the top surface of the turrets, the other part falling into the spaces between each turret; the fabric upon leaving the machine will have the appearance of having furrows cut therein. *Patent completed.*

561. W. BROWN. "Improvements the manufacture of pipe mounts or stems, cigar tubes, and similar articles." Dated March 2, 1859.

The object here is to make the stems of pipes, cigar tubes, &c., of English pipe clay, in lieu of the bone, horn, &c., and ornamenting them either in moulds or by hand, to represent the pipe stems, mounts, or cigar tubes now in use. *Patent abandoned.*

562. H. KONS. "Improvements in articles of wearing apparel called coats." Dated March 3, 1859.

This consists of a coat so cut and arranged as to be worn either as a frock or dress coat. *Patent abandoned.*

563. J. HARRISON. "An improvement or improvements in the construction of rotating window-sashes." Dated March 3, 1859.

This consists in constructing window sashes to turn on centres, so that the outside of the sash may be turned inside, and the inside turned outside. *Patent abandoned.*

564. T. WILSON. "An improvement or improvements in breech-loading fire-arms." Dated March 3, 1859.

The inventor forms at the rear end of the barrel a breech open at top, and of sufficient size to permit of the ready introduction of the charge. On the side of the opening in the breech a cover is hinged, which when shut down closes the opening in the breech. To the cover a bolt or breech plug is attached, the said bolt when the cover is shut down entering and nearly filling in the breech. The said bolt is so attached to the cover that it is capable of a sliding motion in a line coincident with, or parallel to the axis of the fire-arm. A screw bolt passes through the extreme end of the breech, and may be turned by a handle or lever jointed to its end. The charge is introduced at the open breech and inserted in the barrel. The cover with its sliding bolt is shut down upon the opening, and the screw is turned so as to press upon the said

bolt and cause it to close the end of the barrel, when the arm may be discharged. *Patent abandoned.*

565. A. W. HALL. "A new and improved machine for cutting or mincing meat, vegetables, &c." Dated March 3, 1859.

This consists in the use and arrangement of one or more grooved cylinders or rollers revolving in a grooved or ribbed case, and acting against a stationary knife, such grooved cylinders having also tapering or diminishing grooves, so as to prevent the passing of the article until cut finely enough, and also to keep the article continually against the cutting surfaces or knives. *Patent abandoned.*

566. J. D. DOUGALL. "Improvements in fire-arms." Dated March 3, 1859.

This chiefly consists in forming the breech with a solid conical igniting conductor, to ensure the ignition of the charge at the front of the cartridge instead of the back. *Patent completed.*

567. W. JACKSON. "Improvements in shuttles for looms." Dated March 3, 1859.

This consists in a method of constructing the shuttle so as to prevent the cop from flying off; for this purpose the inventor constructs the tongue of tempered steel, and adapts it so as to be fast at both ends upon the shuttle peg. *Patent abandoned.*

568. W. SCOTT. "Improvements in the manufacture of soap." Dated March 3, 1859.

This consists in rendering the fatty and oily matters obtained from wash waters suitable for use in the manufacture of soap by blowing free steam into them to melt them, and washing them repeatedly with weak alkaline solutions or spent lyes, the process being conducted in a pan heated by steam. *Patent completed.*

569. H. LEONARD. "An improvement in the manufacture of paraffine candles." Dated March 3, 1859.

Here the inventor employs a candle mould in which the body and tip matrices are separate from each other, and the tip matrix is applied to the tubular body matrix so as to be capable of being moved therein so as to enable a person by such movement to expel the candle from the mould. *Patent completed.*

570. W. TUCKER. "An improvement in bit stocks or auger handles." Dated March 3, 1859.

This invention is not described apart from the drawings. *Patent completed.*

571. T. COOK. "An apparatus for raising and lowering coffins and bodies, either for burial or disinterment." Dated March 3, 1859.

This consists of a framework with supports which bridge across the grave, together with a winch and straps suitably arranged for lowering and raising the coffins. *Patent abandoned.*

572. W. MITCHELL. "Improvements in discharging cargoes, and in raising and lowering bodies." Dated March 3, 1859.

This consists in taking advantage of the flow of the current (by means of a water-wheel) to accumulate power, by which baskets of coal, &c., may be readily hoisted out of a ship's hold. *Patent abandoned.*

573. C. F. DUNNET. "Improvements in bayonets." Dated March 4, 1859.

This consists in forming bayonets of a lozenge, rhomboidal, elliptic, or other suitable section. The sides of such bayonets may be grooved out so as to reduce the thickness of material in the section, two sharp edges being left throughout the length of the bayonet, the section gradually decreasing from the shoulder to a sharp point. *Patent completed.*

574. M. BIDE. "Improvements in, or applicable to, machines for preparing, spinning, and doubling cotton, and other fibrous materials." Dated March 4, 1859.

This consists in certain combinations of machinery particularly applicable to the machines for spinning called 'throwsters,' the object being to facilitate the operations of doffing the full bobbins, and replacing empty bobbins on the spindles. *Patent abandoned.*

575. J. COWMAN and E. ANDREWS. "Improvements in machinery or apparatus for spinning fibrous materials." Dated March 4, 1859.

This relates particularly to that description of mules in which the mangle motion is used commonly known as "Smith's" plan. The patentees employ a shaft through the headstock for connecting the spindle gearing in each carriage, which shaft is driven by one band for putting the twist in the yarn equally in each carriage. They also use a quadrant similar to that employed in "Sharp and Robert's" mules for procuring a positive winding-on motion; thus instead of two run bands they employ but one, which in connection with the quadrant enables them to have both a positive twisting and winding-on motion. *Patent completed.*

576. R. A. BROOMAN. "An improvement in boiler stays." (A communication.) Dated March 4, 1859.

This consists in a method of forming boiler stays of cylinders or tubes passed through enlarged rivet or bolt holes, and afterwards expanded at the ends adjacent to such holes. *Patent completed.*

577. C. R. MEAD. "Improvements in water gas meters." Dated March 4, 1859.

This invention is not described apart from the drawings. *Patent completed.*

578. W. and J. BAILES. "An improved ship's berth for the prevention of sea-sickness, composed of wood and metal." Dated March 5, 1859.

This invention is not described apart from the drawings. *Patent completed.*

579. J. M. DUNLOP. "Improvements in machinery or apparatus for cleaning fibrous materials." Dated March 5, 1859.

The object here is to make the "Mc Arthy Gin" suitable for working by manual labour. The patentee applies a first motion shaft carried in bearings fixed to the gin sides on each end of which he fixes a handle; on one end of the said shaft, and immediately behind the handle, he fixes a spur wheel which drives or gears into a spur pinion fixed in the roller covered with leather usually used in the above-named gins. These wheels are of the necessary respective diameters to obtain sufficient speed for the efficient working of the gin when driven by hand. *Patent completed.*

580. J. LEIGH. "Improvements in the purification of coal gas." Dated March 5, 1859.

This consists in the application of causticized gas water or ammonia water to the purification of coal gas or camel gas. The patentee effects this by passing the gas through the gas water in suitable vessels, to remove from the gas not only the salts of ammonia existing therein, but also the carbonic acid, sulphuretted hydrogen, sulphocyanic acid, &c., which may exist also in the impure gas. *Patent completed.*

581. J. FRASER. "Improvements in ploughs." Dated March 5, 1859.

This consists in manufacturing the mould boards of ploughs so as to have one portion harder than the rest. The part exposed to severe wear is chilled in the casting, whilst the other part is left soft. *Patent completed.*

582. F. W. PARKER. "Improvements in sewing machines." Dated March 5, 1859.

Here the patentee employs a needle with an eye near the point, and attached to a piece of metal sliding up and down in a guide, and driven by a crank. The needle moves up and down through the work which is laid upon a table with a hole for the passage of the needle. Below the table is a hook or looper capable of turning on a horizontal axis or spindle, which has also an end motion. When the needle has passed through the work, and commences to rise again, the thread bends or bows out at its side, and the hook is then passed through the loop thus formed. The spindle of the hook or looper receives an end motion as soon as the looper has passed the side of the needle, and the looper is caused to hold or present the loop in a line with the seam so that the needle is sure to pass through it in its next descent. When the needle has thus entered the loop, the looper slides sideways, and partially turns on its own axis so as to bring it back to its original position. The motions are then repeated, and the looper now enters the new loop and holds it as before. *Patent completed.*

583. E. VIGERS. "Improvements in the construction of ships and other vessels." Dated March 5, 1859.

This consists in a novel combination of wood with iron in constructing the frames of ships, by which greater strength combined with other advantages is secured. *Patent abandoned.*

584. W. P. SAVAGE. "An improved machine for excavating, raising, and depositing soil." Dated March 5, 1859.

Here the earth is raised by two sets of iron cups or buckets revolving upon axes. The two sets of cups descend into the land at different depths; one set is arranged to cut into and remove the upper surface, and the other set to cut into and raise the earth from below. *Patent completed.*

585. F. VERDEIL and E. MICHEL. "Improvements in treating madder." Dated March 5, 1859.

This consists in treating madder with an alkaline liquid, then in exposing it when in contact with the alkaline liquid to the action of air to oxidise it, and in afterwards boiling the madder thus prepared in acid. *Patent completed.*

586. G. LEACH. "Improved machinery for reeling and leashing yarn or thread." Dated March 5, 1859.

This relates to machinery whereby yarn or thread may be reeled into hanks, and in doing which the threads are made to cross each other so as to form a

crossing at or near the centre or other convenient part of the hank. *Patent completed.*

587. F. MORRIS. "An improvement in the construction of strained fences." Dated March 5, 1859.

The inventor proposes to draw the strands, cords, wires, wire rods, hoops or bands of strained fences up to tension by passing them through rollers, barrels, or pulleys provided with any convenient contrivance whereby rotary motion may be communicated to them. *Patent abandoned.*

588. R. LEAKE and M. SYKES. "Improvements in furnaces for consuming smoke and generating heat, parts of which improvements are applicable to furnaces generally." Dated March 5, 1859.

This relates to a former patent dated 1st May 1857, and is based on the fact that 4-5ths (by weight) of water is oxygen, and, bulk for bulk, water is 825 times heavier than common air, so that when 4-5ths are taken from the gross weight of water it gives 600 times more oxygen in one inch of water than is contained in atmospheric air of the same bulk, and when water (in proper quantity) is introduced to the fires in furnaces of steam boilers through the spaces between the fire bars, instead of having a cooling effect it will give off a large quantity of gases, and produce a more intense heat than can be produced in any other way except where means similar to those employed in blast furnaces are adopted. *Patent completed.*

589. H. W. PATRICK. "An improvement or improvements in an apparatus for chemical and dental laboratories, or other manufacturing or experimental uses, which he proposes calling a 'paragon laboratory forge.'" Dated March 7, 1859.

This consists in the construction and arrangement in an apparatus of a smelting furnace, an annealing furnace or oven, a digester with a dry hot bath for dry heats, a sand bath, and a steam bath, a brazing lamp, to be used separately or detached, and portable; and the whole so constructed as to be heated by coal-gas or any other gases or fuel, and by means of a portable funnel to connect the same with the flue of a chimney; or it can be used without such connexion. *Patent abandoned.*

590. D. PROUDFOOT. "Improvements in Turkey-red dyeing." Dated March 7, 1859.

This relates to the application and use of the fruit of the velam tree or Turkish oak in the preparing and dyeing of cotton cloth and yarns according to the Turkey-red process. *Patent abandoned.*

591. A. CABANY. "A new system of quoins (wedges) for railways." Dated March 7, 1859.

The inventor substitutes for the ordinary quoin or wedge used to maintain railway chairs and rails in position, one which he terms a double or twin wedge, so arranged that the parts shall, as it were, dovetail, the traction and lateral jerks of the rolling stock at speed serving more securely to fix the combination of rail-wedge and chair together. *Patent abandoned.*

592. W. PALMER. "An improved railway carriage break, and coupling apparatus connected therewith." Dated March 7, 1859.

Here each carriage carries its own apparatus and each wheel is locked by means of a friction wheel or pulley, so that a long train may be stopped in as short a time as a short train. *Patent completed.*

593. F. AYCKBOURN. "Laminating india-rubber cloths with paper sheets." Dated March 7, 1859.

This consists in coating the surfaces of suitable fabrics, and also the surfaces of sheets of paper, with india-rubber solution, bringing the solutioned surfaces together, and passing the whole between rollers. *Patent abandoned.*

594. W. GOSSAGE. "Improvements in the treatment of certain ores of copper for the extraction of metals therefrom." Dated March 7, 1859.

The patentee claims, 1, a combination of processes by which he extracts copper and oxide of iron (suitable for the production of malleable iron) from burned sulphurous copper pyrites, by the use of per-salt of iron in solution, which per-salt of iron is by such extraction of copper reduced to the state of proto-salt of iron, and which combination of processes or operations includes the conversion of proto-salt of iron so produced into per-salt of iron, by exposing it when in a dry state to the action of heat and atmospheric air; also the application of such combination of processes and use of per-salt of iron together with common salt to the extraction of silver from such burned sulphurous copper pyrites as contain silver. 2. The use of per-salt of iron contained in the "muro waters" used for extracting copper from the burned sulphurous copper pyrites. 3. The use of metallic iron, and of proto-sulphuret of iron, both obtained from the burned sulphurous copper pyrites for the precipitation of copper from solutions containing such metal. *Patent completed.*

595. J. ASPINALL. "Improvements in evaporating in vacuo." Dated March 7, 1859.

The patentee claims evaporating in vacuo by means of steam or hot-air pipes whether free to rise and fall or stationary, maintained at the upper part of the vacuum pan, or at or about the surface of the liquor or substance to be evaporated. *Patent completed.*

596. P. E. AIMONT. "Improvements in the construction of waggons and other carriages for railways and ordinary roads, and of apparatuses connected therewith." Dated March 7, 1859.

The patentee claims, 1, a method of constructing waggons or carriages so that the wheels of the same shall be able to pass over any inequalities in the ground or round a curve without the body of the waggon, &c., departing from its vertical position. 2. The employment of rails with an upright tongue, and with a bottom having sloping sides, such rails being for waggons or other carriages to travel on, together with a method of attaching or linking the same together and fixing them to the ground. 3. The employment of an instrument provided with a plumb-weight to indicate the gauge of the way and the position of the rails. 4. The employment of a single line of rail in the middle of the rail or tramway as described. *Patent completed.*

597. J. ORR. "Improvements in weaving ornamental fabrics." Dated March 7, 1859.

This relates to a previous invention patented 23rd April, 1855. One part of the present invention consists in laying two shoots in place of one into each shed of the inner warp. Another part consists in producing fabrics of a similar description, but having one face only. *Patent abandoned.*

598. J. P. CLARKE. "Improvements in the manufacture of reels for the winding on cotton, linen, threads, silk, or other fibrous materials." Dated March 7, 1859.

This consists, 1, in inlaying discs or rings of bone, or ivory into the ends of reels. 2. In covering the ends of reels with a flanged disc of bone or ivory. 3. In forming holes in the cylinders of reels, which holes will show the extent of cotton, &c., the reel contains. 4. In making reels with two or more compartments, so as to wind cotton, &c., of different sizes or colours upon the same reel. *Patent completed.*

599. J. L. JULLION and G. PRIE. "The manufacture of gelatine." Dated March 7, 1859.

This refers to the treatment of bones so as to obtain therefrom gelatine in a solid form, and consists in chemically separating the constituent parts thereof by causing them to be first cut or broken, and subsequently submitted in vacuo to the action of such acids as are suitable for forming soluble compounds of phosphate of lime. *Patent completed.*

600. J. KING and A. WILCOCK. "Improvements in certain parts of machines used in preparing, spinning, and doubling cotton and other fibrous materials." Dated March 8, 1859.

This consists in a mode of weighting and cleaning the drawing rollers. The top rollers are made so heavy that the hooks and weights may be dispensed with, and they are covered with flannel that the cleas may be dispensed with. *Patent abandoned.*

601. A. BOOTH and A. BOOTH, jun. "Improvements in machinery or apparatus for making or manufacturing tags for laces." Dated March 8, 1859.

The patentee employs a series of circular shears or cutters placed the length of the tag apart, so that the metal may be cut into several strips at once, which are coiled upon spools as the cutting proceeds. Any suitable number of the said coils are then placed in a creel, and the strips brought to a machine adapted for cutting, punching, and finishing several tags at one revolution of the driving shaft. The said machine is furnished with a number of circular or other formed feeders for guiding and feeding the strips at a speed according to the desired size of the tag, the various sizes being regulated by change wheels. The measured lengths of the strip are cut, shaped, punched, and afterwards released by means of sliding movements effected by the compound action of cranks, ex-centrics, or cams, a vibrating or sliding gauge being employed to regulate the shape of the tag. *Patent completed.*

602. W. HALLIDAY. "Improvements in apparatus for preventing smoke and economising fuel." Dated March 8, 1859.

This consists in placing inside the boiler or other flues, a short distance behind the bridge, an apparatus composed of a suitable number of fire-clay tubes of from two to three feet in length, fitted into and between two end pieces of fire-clay. *Patent abandoned.*

603. G. TWIGG. "An improved fusee-igniter for the use of smokers." Dated March 8, 1859.

This consists in the construction of a small apparatus for the pocket, which apparatus shall form a safe receptacle for fuses, and also a self-acting

igniter, so that a person may be enabled to carry with him a large number of fuses in small compass, and readily obtain a light without breaking the fusee or burning the fingers. *Patent completed.*

604. C. MILLS. "Improvements in the action of pianofortes." Dated March 8, 1859.

Here the fly, as heretofore, is hinged at its lower end to a block fixed in a key of an instrument, as is also, as heretofore, pressed back by a suitable wire spring. At the front of the block is formed a stump which rises above the block, and the fly has a screw fixed into it at a point above the hinge. The screw passes through a hole formed in the stump in the block, and has mounted on it a button or stop which comes against the stump so as to stop the fly at the point required. *Patent completed.*

605. J. N. RYDER. "Improvements in preserving fruits, and in apparatus used for such purposes." Dated March 8, 1859.

Here the fruit is placed in a suitable vessel, to which heat can be applied by a steam jacket, and from which the air and vapour can be removed by an air pump. Around the upper edge of the vessel a hollow groove is formed to receive the lower edge of a dome-shaped cover. At the bottom of the hollow groove is a ring of vulcanised india-rubber, so that when the cover is pressed down by the external atmosphere the joint will be sufficiently air-tight. *Patent abandoned.*

606. E. DEANE. "Improvements in apparatus for the transmission of gas and other fluids." Dated March 8, 1859.

This consists in placing a screw, or threaded rod, or wormed plug within the bore of the pipe used for transmitting gas, &c., from the reservoir to the point of use. *Patent abandoned.*

607. W. CLARK. "Improvements in submarine telegraph cables." (A communication.) Dated March 8, 1859.

This consists in winding a copper wire spirally round the cable, and of placing one of the extremities of this wire in communication with one pole of the pile and the other extremity with the ground, whereby the inventor believes several advantages to be obtained. *Patent abandoned.*

608. B. M. BELLING. "Improved apparatus for hardening india-rubber for the bases of teeth." Dated March 8, 1859.

This consists of a wrought iron chamber of rectangular form, furnished with perforated shelves. The bases are subjected in this chamber to certain degrees of heat. *Patent abandoned.*

609. J. PILBROW. "Certain improvements in, or a new method or methods of, obtaining and applying motive power, a modification of which is also applicable for pumping or forcing liquids, gases, and fluids, as also for measuring liquids, gases, and fluids." Dated March 8, 1859.

Here a flexible and elastic tube is placed between two rollers, the rollers being pressed together with a force (by the agency of springs) sufficient to close the tube at the point where such rollers are placed. One end of the tube is left open to the atmosphere, and the other end is in connection with an air-pump. Upon the air being exhausted from the tube it will collapse; thus will the rollers be placed out of equilibrium as respects the pressure or elastic force of the tube on either side of them, and hence they will move over the collapsed part of the tube. *Patent abandoned.*

610. J. A. WILLIAMS. "Improvements in machinery or apparatus for cultivating land by steam power." Dated March 9, 1859.

This invention comprises various features in connection with agricultural implements. The specification is too elaborate for us to quote it at sufficient length for an intelligible abstract. *Patent completed.*

611. Sir W. G. ARMSTRONG. "Improvements in rifle ordnance and its projectiles." Dated March 9, 1859.

This invention was described at page 199, No. 39, Vol. 2, of the MECHANICS' MAGAZINE (New Series). *Patent abandoned.*

612. J. R. NICHOLSON. "New or improved machinery to be used in the manufacture of needles, a part or parts of which said machinery may also be used for pointing pins, and other like articles." Dated March 9, 1859.

This consists of machinery in which the wires to be operated upon are pointed by the action of grinders, the said wires being previously cut or ground of uniform length where necessary, and when the said wires are to be converted into needles, operated upon after the grinding processes by means of dies which produce the gutter and the impress of the eye of the needle. *Patent completed.*

613. J. ERWOOD and J. SKERTCHLY. "Improvements in the manufacture of glass, sand, and emery

papers and cloths, and other similar articles used for like purposes." Dated March 9, 1859.

In these improved abrading papers and cloths, the patentee raises or depresses certain portions of their surfaces by embossing or otherwise, producing lines, patterns, indentations or other forms upon them in order to destroy their level character. The object is that in their use the portions highest in relief are brought in contact with the substance to be abraded first, and as these portions are gradually worn away, fresh and unworn parts of the papers or cloths are successively brought into action until the lowest part are finally worn out. *Patent completed.*

614. G. C. PEARCE. "An improvement in cornets, trumpets, trombones, and other like wind instruments." Dated March 9, 1859.

The object here is to reduce the number of bends in brass and other metal instruments, and to cause the air to travel through the same number of bends whether the keys are up or down. This the inventor effects by one bent or semicircular passage, and two straight passages in a moveable valve placed in a box or cylinder. By turning the valve in one direction the wind enters and returns by and through the bent passage, while on turning it in the other direction, the straight passages through the valve are opened to the passage of the wind. *Patent abandoned.*

615. J. S. RUSSELL. "Improvements in building ships and other vessels." Dated March 9, 1859.

This invention was described at page 199, No. 39, Vol. 2, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

616. J. COOKE. "Improvements in apparatus for giving signals on railways and vessels, and other such like uses." Dated March 9, 1859.

Here an air tight vessel is filled with air by means of an air pump, and a whistle is blown by the action of the air therein. *Patent abandoned.*

617. A. V. NEWTON. "Improved machinery for rolling horse-shoe iron." (A communication.) Dated March 9, 1859.

Here the inventor combines in a pair of rolls a groove and crossers, which, by their joint operation, exert pressure in a lateral as well as in a longitudinal direction, and thus produce, by a continuous operation, horse-shoe iron, which is concave on its upper side, thin on its inner edge, thick on its outer edge, creased on its under side, and gradually diminishing in width from heel to toe. *Patent completed.*

618. W. E. NEWTON. "Improvements in billiard tables." (A communication.) Dated March 9, 1859.

This consists, 1, in supporting the rail by rhomb-shaped studs which leave room enough in their centre for bolts to pass through, while they are bevelled down towards both ends, so that an open space is left between the bed of the rail nearly all the way round, so that a ball can be reached with a cue just as easily when it lies close up to the cushion as it can when it lies further from the rail. 2. In forming the pocket bows of the same pieces which form the rail, joining the same in the middle of the bows, and giving them a bevel underneath, so as to throw the balls down when played at the pockets, and yet keeping the pocket bow on a line with the top of the rail. 3. In a particular construction of the cushion, the object being to give a perfectly true angle. *Patent completed.*

619. H. FISHER. "Improvements in machinery or apparatus for cutting thin sheets of metal into strips, and for tempering sheets or strips of metal." Dated March 9, 1859.

This consists in preventing thin strips of metal from twisting or curling during the process of cutting them from the sheets by rotary cutters, by causing a bar to press the material upon the said cutters, which material also passes between rollers. Also in the use of rollers for keeping strips or sheets of metal at tension during the process of tempering. *Patent abandoned.*

620. J. C. MARTIN. "An improvement in the manufacture of cannon and small fire-arms, and of projectiles to be used with the same." Dated March 10, 1859.

This consist in forming a smooth chamber at the breech of the gun by increasing the diameter of the bore of a rifle to the depth of the grooves, or rather more so, and in length slightly greater than the projectile to be used; a chamber for the powder somewhat less than the bore may be formed at the breech of the previously-described chamber. The object of increasing the diameter of the bore at the breech is to admit at the mouth of the gun a projectile that shall on reaching the chamber expand and fill it, and be forced by the action of the powder into the grooves, closely and perfectly filling them as the gun is discharged. The projectile on reaching the chamber consists of two parts, viz., a conical plug of iron somewhat in the form of a sugar-loaf, and an outer

moveable casing of lead or other suitable soft material. *Patent abandoned.*

631. J. YULL. "Improvements in saddle-trees." Dated March 10, 1859.

Each saddle-tree or curb, according to this invention, is cast wholly in a solid piece, as near as can be to the ultimate bend required, and it is afterwards bent to the exact form necessary. *Patent completed.*

632. R. F. WOODWARD. "An improvement or improvements in the manufacture of certain kinds of scale beams and fittings used therewith." Dated March 10, 1859.

This relates to scale beams made of iron or steel, and consists in making them by the process of stamping instead of by forging. *Patent abandoned.*

633. H. LODGE. "Improved means of protecting ships, batteries, and other constructions or buildings from the effects of projectiles of various kinds." Dated March 10, 1859.

This consists in the use of corrugated sheets of metal. *Patent completed.*

634. J. H. BURTON. "An improvement in breech-loading fire-arms." Dated March 11, 1859.

This consists in constructing the steel or iron breech-plug, so that the part coming in contact with the explosive force of the powder is separated from the main portion by interposing a cylinder or ring of copper or other suitable metal, and all are secured together by a screw or other device. *Patent abandoned.*

635. J. C. HADDAN. "Improvements in casting mortars and cannon." Dated March 11, 1859.

This consists in causing the mould to revolve either during the time that the metal is being poured into it, or afterwards, until it has become partly or entirely solidified. *Patent abandoned.*

636. R. HELLARD. "Improvements in reaping and mowing machines." Dated March 11, 1859.

The object here is to effect a better raising than heretofore of laid or beaten-down corn, and bringing it up into or towards the knives or cutting apparatus of the machine, and thus placing it in a more favourable position to its being cut, and further correctly disposed of, and this object is effected by the use of creepers made of iron or other suitable material. *Patent completed.*

637. S. WHEATCROFT. "Improvements in the construction of goffering and rouching machines, in order to render them self-registering and self-indicating." Dated March 11, 1859.

This consists in appending apparatus to the goffering or rouching machine, so that it shall itself indicate when the determined quantity has passed through the machine, and also that it will, if necessary, cut off this goffered portion, which will then contain the predetermined length, and also that when necessary by additional indicating apparatus, it will show the amount of plain material that has passed through the machine in a given time. *Patent completed.*

638. N. WASHBURN. "A new and useful or improved machine for rolling tyres for wheels." Dated March 11, 1859.

This invention consists in a combination of a set of reducing rollers, a series of adjustable carrying rollers, and a frame or holder of the carrying rollers, supported so as to be capable of rising upward within the wheel-tyre in proportion as the diameter of the inner periphery of the tyre increases during the rolling of the tyre. *Patent completed.*

639. F. CLARK. "An improved mode of, and apparatus for, cutting, drying, and preparing peat to be used as fuel, or for other purposes for which it may be usefully employed." Dated March 11, 1859.

Here the patentee cuts large slices of peat of about 3 feet wide, from 12 to 18 inches thick, and from 15 to 30 feet long by means of an apparatus which consists of a cutting tool of suitable form, and provided with a long handle or shaft. This cutting tool is worked by toothed or other suitable gearing. The slabs of peat having been pressed and solidified are put upon a travelling web made of metal, and passed into or slowly through long narrow drying chambers constructed of brick, stone, iron, &c. *Patent completed.*

630. A. V. NEWTON. "An improved construction of steam-engine, applicable also to the raising of water." (A communication.) Dated March 11, 1859.

This invention is not described apart from the drawings. *Patent completed.*

631. J. CUNLIFFE, F. PIGGOTT, and G. MALLINSON. "Improvements in the manufacture of ornamental woven fabrics." Dated March 12, 1859.

Here fabrics are woven by any suitable mechanism with the web floating over the warp, so as to leave spaces, and the ornamental velvet effects or patterns required are produced by cutting parts of the faces

and leaving the other parts uncut. *Patent completed.*

632. W. E. NEWTON. "An improvement in endless chain propellers for boats and other vessels." (A communication.) Dated March 12, 1859.

This consists in attaching the chains to the buckets of endless chain propellers at points in, or nearly in lines passing longitudinally or horizontally through the centres of the faces of the buckets, and in bracing the so attached buckets to the links of the chains by diagonal braces attached to opposite sides of the buckets, and on opposite sides of such central lines. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated June 20, 1859.

1478. L. D. Dewey. Improvements in spring seats for chairs, sofas, couches, carriages, and other similar articles. (A communication.)

Dated July 4, 1859.

1589. H. C. Howells and J. C. Howells. Improvements in the mode of registering the number of persons entering or leaving public conveyances or places of public resort, and of determining the value of the entry or fare.

Dated Aug. 27, 1859.

1957. J. Philp. Improvements in the manufacture of soap. (A communication.)

Dated Aug. 29, 1859.

1959. J. Whitworth. Improvements in ordnance, fire-arms, and ammunition.

1964. J. Edwards. Improvements in the manufacture of buttons.

Dated Aug. 31, 1859.

1989. R. A. Brooman. Improvements in treating auriferous and argentiferous ores and substances. (A communication.)

Dated Sept. 3, 1859.

2014. W. Suffield. Improvements in the manufacture of artificial teeth, and in machinery to be employed in the said manufacture.

2018. G. Davies. Improvements in printing, and in apparatus connected therewith. (A communication.)

Dated Sept. 7, 1859.

2038. E. R. Dann and E. Goldschmidt. Improvements in the manufacture of bonnet fronts or lappets.

2040. H. Jones. Improvements in breech-loading fire-arms.

2042. J. L. Jullion and G. Pirie. The manufacture of gelatine, and apparatus to be employed therein.

2044. A. V. Newton. An improved manufacture of metallic strips or bands applicable to ladies' skirts. (A communication.)

2048. W. Rothwell and T. Watson. Improvements in screw gill-boxes.

Dated Sept. 8, 1859.

2050. T. O. Small. Improvements in the stereoscope, by means of tinted media, and by the application of the pulley and lever, or spring, in changing the lights.

2052. J. H. Johnson. Improvements in cocks and valves. (A communication.)

2054. J. Tandy. Improvements in locomotive and other steam-boilers.

2056. G. Gowland. Improvements in nautical and surveying instruments for measuring angles.

Dated Sept. 9, 1859.

2060. S. Worresam. Improvements in sawing machinery.

2062. W. E. Gedge. Improvements in the manufacture of nails. (A communication.)

2064. A. V. Newton. Improvements in the process of, and machinery for, manufacturing hat bodies. (A communication.)

Dated Sept. 10, 1859.

2066. A. Smith. Improvements in strengthening umbrella and walking stick handles, and other articles or details wherein the cross or transverse grain of wood or other material is subject to strains.

2068. W. Ross. Improved apparatus connected with the discharge of liquids.

2069. E. J. Mallett. Improvements in axles.

2070. T. J. Perry. An improved construction of hot air oven.

Dated Sept. 12, 1859.

2076. J. Eason. Improvements in the manufacture of buff or loth and other oiled leathers.

2078. W. H. Morrison. Improvements in the manufacture of bonnet and cap fronts, and in the means or apparatus employed therein.

2080. J. Mason. An improvement in boxes or cases and cards to contain or hold pens.

2082. W. Elliott. Improvements in the manufacture of African or Guinea rods.

Dated Sept. 14, 1859.

2091. C. G. Gumpel. Improvements in the application of motive power to the propelling of vessels.

2093. J. P. Kennedy. Improvements in steam-boilers.

2095. C. Beslay. Improvements in preparing and obtaining printing surfaces with designs, sunk as also in relief.

2097. J. S. Slocum. Improvements in projectiles, suitable for ordnance. (A communication.)

Dated Sept. 15, 1859.

2099. J. Robinson. An improved agricultural implement.

2101. J. Brière. Improvements in railway breaks.

2103. H. Winter. A machine or apparatus for lifting and weighing loaded sacks, and also merchandize.

Dated Sept. 16, 1859.

2105. J. W. Hadwen. An improvement or improvements in apparatus or machinery used for drawing fibrous substances or material in any of the processes or machines for preparing to be spun, or for spinning the same.

2107. N. Hockford. A method of purifying the Thames and other rivers, and of treating night soil.

2109. W. E. Newton. Improvements in machinery for forming hat bodies. (A communication.)

2111. H. Jackson. Improvements in fire-bars.

Dated Sept. 17, 1859.

2113. J. Luis. A new brick and tile-making machine. (A communication.)

2115. J. Luis. Further improvements in breaks for railway carriages. (A communication.)

2117. J. Luis. A slip bridle for stopping runaway horses. (A communication.)

2119. J. Luis. An improved disc and lantern signal with double repeaters. (A communication.)

2121. S. N. Rodier. Improvements in the regulation of gas to burners, which he calls "Rodier's regulating gas valve."

2123. A. J. Norman. Paving roads and surfaces.

Dated Sept. 19, 1859.

2125. F. N. Gisborne. Paying out submarine telegraph cables.

2127. W. Robertson and J. Tweeddale. Improvements in hydrostatic jacks, or lifting apparatus. (A communication.)

2129. J. Wright. Improvements in the construction of carriages, coaches, omnibuses, and other such like conveyances. (A communication.)

2131. P. Fairbairn. Improved machinery for finishing the teeth of spur and other gearing.

2133. R. A. Brooman. Improvements in elevators or lifts for hotels, warehouses, and other structures. (A communication.)

2135. L. Engler and E. F. Krauss. A new or improved system of insulators for electric wires.

Dated Sept. 20, 1859.

2139. W. Weild. Improvements in fluted rollers used in machines for preparing, spinning, and doubling cotton, wool, flax, silk, and other fibrous materials, and in the manufacture of such rollers.

2141. J. Beads. Improvements in machinery or apparatus for spinning cotton, wool, and other fibrous substances, part of which improvements is applicable to other purposes.

2143. W. E. Newton. Improvements in projectiles. (A communication.)

2145. E. Collier. Improvements in ear dilators.

Dated Sept. 21, 1861.

2147. H. Corless. Improvements in apparatus for washing, wringing, and mangling.

2151. W. E. Newton. An improved mode of, and apparatus for, condensing the waste steam of marine engines. (A communication.)

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2154. E. B. Dimock and J. H. Baker. A new and useful improvement in mechanism or apparatus for drying woollen or other cloths. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Oct. 4, 1859.)

1240. J. Valda. Stud-fastenings.

1244. G. J. Parfitt. Gas burners.

1253. J. R. Scartiff. Lubricating cans.

1261. J. Knowles. Power looms.

1280. J. Gibbs. Treating coal, &c.

1282. G. Hadfield. Heating and evaporating.

1290. E. Maw. Metallic bedsteads.

1298. J. Webster. Gauges.

1304. G. F. Chantrell. Charcoal kilns.

1306. J. Draper. Indices.

1311. W. Weild. Pile fabrics.

1314. L. Farrer and B. Subra. Gas lighting.

1315. H. N. Nissen. Indexes.
1316. G. Hadfield. Casks.
1328. J. Bruce. Drills.
1331. O. Maggs. Harrows.
1332. W. Green. Treating sugar.
1344. G. M. Smith. Sewing machines.
1345. P. Gambardella. Obtaining motive power.
1348. F. and A. Roberts. Cultivating land.
1351. F. W. Saltonstall and A. Bush. Dredging.
1363. R. W. Sivier. Smelting.
1365. R. Mushet. Iron and steel.
1379. C. James. Railway chairs.
1395. C. de Bergue. Shearing metal. (Partly a communication.)

1402. W. Burness. Steam-culture machinery.
1430. E. J. Maumené and V. Rogelet. Potash.
1500. C. F. and C. J. Varley. Electric conductors.
1522. P. Faure and J. Pernod. Maddler.
1737. J. Hinks and G. Wells. Dress fastening.
1757. T. Culpin. Water-closets, &c.
1789. R. A. Brooman. Mills. (A communication.)
1820. E. T. Hughes. Chenille. (A communication.)
1886. W. Leatham. Screw throttle valve.
1910. R. A. Brooman. Spinning. (A communication.)

1985. A. Smith. Cocoa nut fibre.
1993. P. Wright. Anvils.
2059. J. G. N. Alleyne. Wrought iron beams.
2064. A. V. Newton. Hat bodies. (A communication.)
2071. T. G. Gutch. Copying books.
2080. J. Mason. Cases and cards for pens.
2081. H. G. Collins. Printing blocks and inks.
2089. W. E. Newton. Drying fabrics. (A communication.)

2109. W. E. Newton. Hat bodies. (A communication.)

2111. H. Jackson. Fire bars.
2131. P. Fairbairn. Teeth of gearing.
2154. E. B. Dimock and J. H. Baker. Drying cloths. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS. *

Scaled Sept. 29, 1859.

707. J. Cartwright.
708. C. P. Coles.
801. W. and E. Smith.
807. A. Morton.
813. D. K. Clark.
814. F. P. A. Auburtin.
822. Y. Thomas.
824. A. Ripley and J. Roberts.
832. M. Coupland.
834. T. Williams and J. H. Fuller.
836. J. Eccles.
840. J. H. Burton.
843. C. Russell.
844. M. A. Crooker.
846. E. Morewood.
848. A. Shanks.
850. E. Fairburn.
852. F. C. Bakewell.
853. G. F. Chantrell and E. Dutch.
855. J. Hetherington, T. Webb, and J. Craig.
861. J. A. H. Ballande.
862. W. Owen.
864. J. Scoffern.
865. D. Moseley.
871. J. Garrett.
873. J. T. Pitman.
878. M. A. F. Monnons.
880. N. A. Grunel.
883. W. Henderson.
885. E. R. Handcock.
886. T. Spencer.
891. J. H. Johnson.
895. W. E. Newton.
934. J. Gillett.
957. W. E. Newton.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

RAILWAY, Manchester, Sheffield, and Lincolnshire.—The directors will receive tenders for construction of a branch railway commencing near the town of Hyde, and terminating near Murple, Chester. Plans and specifications, Oct. 13, at the office of Mr. John G. Blackburne, C.E., Oldham, from whom all necessary particulars. Tenders to Mr. Edward Ross, Secretary.

RAILWAY PIER, Sittingbourne and Sheerness.—For construction of a pier at Queenborough, Isle of Sheppey. Drawings, &c., and form of tender, at office of the engineer, Mr. J. C. Birkinshaw, 22 Abingdon-street, Westminster. Tenders to Oct. 10.

SEWER WORK, St. Luke, Chelsea.—For the execution of general works connected with the sewers and drains, according to a schedule of prices at the office of the vestry, Manor House, 111 King's-road, Chelsea. Contract for twelve months. Copies of the schedule, and of the contract, and form of tender, at the vestry offices, upon payment of 10s., to be returned to parties tendering. The vestry reserve the right of making special contracts. Tenders at the offices, Oct. 10.

WIDENING BRIDGE, Droylsden.—The Board of Surveyors for the township of Droylsden are now ready to receive tenders for the widening of Fairfield Bridge, in the said township. Plan and specification, Mr. James Hadfield, assistant surveyor, Ashton-lane, Droylsden, to whom tenders, 15th Oct.

CONGREGATIONAL CHAPEL AND SCHOOLS, Cheshire.—Conditions, plans, and specifications, Oct. 11, Mr. Isaac Neill, 24 Brown-street, Manchester. Tenders to the Building Committee at Mr. Neill's office, Oct. 19, 4 p.m. Information and bills of quantities, Messrs. Poulton and Woodman, architects, Reading; London-road station, Manchester; 12 a.m., Oct. 27.

CEMETERY CHAPELS, Great Malvern.—For the erection of the proposed chapels and buildings for the cemetery of Great Malvern. Plans, &c., vestry room of the Priory Church, by applying to the Churchwardens. Further information of the architect, Mr. W. H. Knight, Cheltenham. Tenders to the Churchwardens, Oct. 12.

CEMETERY CHAPELS, South Weald, Essex.—For the erection of a chapel, lodge, and fences, and the laying out the intended burial ground, situate in the parish of South Weald, near the road leading from Brentwood to Warley. Plans, &c., at the office of Mr. T. E. Knightley, 25 Cannon-street, London. Tenders to Oct. 18.

SCHOOLS, Pelston, in Nottingham.—For the erection of boys' and girls' schools with offices. Drawings, &c., also bills of quantities on application at the office of the architect, Charles H. Edwards, 4 St. James's-terrace, Camden Town, N.W., or at the rectory, Pelston. Tenders to October 14.

WAREHOUSE, Great Malvern.—For pulling down certain premises at No. 5 Copenhagen-street, and erecting a warehouse on the site thereof. Plans, &c., at the vestry room of the Priory Church, on application to the churchwardens. Further information from the architect, Mr. W. H. Knight, of Cheltenham. Tenders to Oct. 12.

CONTRACTORS' RAILS, London.—Must be 33 lbs. to 40 lbs. Apply J. B. Brown and Co., 18 Cannon-street, City, London, E.C.

MAGISTRATE'S ROOM AND POLICE STATION, Daventry, Northamptonshire.—For the erection of a magistrate's room and police station at Daventry. Plans, &c., at the office of Mr. James Milne, county surveyor, Northampton. The tenders must be made in two parts, one stating the amount for the police station, and the other the amount for the magistrate's room. Tenders to Oct. 17.

GAS FITTINGS, Stone, Staffordshire.—The churchwardens of Stone parish church are desirous to receive specifications and tenders to contract to supply and set up the necessary fittings for lighting the church with gas in the most approved manner. The area of the church is 70 feet by 54 feet; height, 34 feet; roof flat. No pillars or columns, saving the iron ones, which support the galleries on three sides. Address, the churchwardens.

WORK AND MATERIALS, St. Luke, Chelsea.—For the execution of works and the supply of materials connected with the trades of paviors, masons, stone merchants, and others, in the parish of St. Luke, Chelsea, as may be required and directed. Further particulars and forms of tender of Mr. Charles Lahee, vestry clerk, offices, Manor-house, 111 King's-road, Chelsea; where tenders, Oct. 10.

IRON BORINGS AND TURNINGS, War Office.—Tenders will be received at this office, on or before the 10th October, for the purchase of iron borings and turnings from the Royal gun factories, Woolwich. Tenders must be made upon the proper printed form, which may be obtained at this office, or to the superintendent of the Royal gun factories, from whom all information respecting the iron may be obtained. All tenders to be addressed to the Under Secretary of State for War.

OILS, Navy.—For supplying Her Majesty's several dockyards with Gallipoli oil, linseed oil, and English or Russian white tallow. Distributions of articles and forms of tender, Somerset-place. Tenders with presence of principal or agent; and bond-letter to the extent of £25 per cent. of the tender, two o'clock, Oct. 11.

OIL, Navy.—For supplying Her Majesty's several dockyards with train or pitchard oil, and pale seal oil. Distributions of the oils and forms of the tenders at the office of the Storekeeper-General of the Navy, Somerset-place. Tenders, Oct. 18, 2 p.m., per principal or agent. One bond for £100 for the due performance of the contract for train or pitchard oil, and £150 for pale seal oil.

CAST-IRON PIPES, Somerset.—Some cast-iron pipes wanted for hot water, gas, and steam. Also rain, gutter, and wall pipe. Apply to Mr. W. Bishop, iron and beam foundry, Wellington, Somerset.

PLANS FOR CHURCH, Stroud.—For designs, specifications, and estimates for rebuilding the parish church, Stroud. The church to contain 1,500 sittings, 500 of which are to be free, and the cost not to exceed with the old materials £4,000. The old tower and spire to remain; the south, north, and west walls to be built on their present foundations, and if necessary, south, north, and west galleries to be constructed. The chancel to be enlarged, and the floor of the church and chancel to be raised. An organ chapel and vestry to be constructed at the side or sides of the chancel. A premium of £20 will be given for the approved design. Plans to be forwarded to Messrs. Sidney, Biddle, and George Edwards, Hon. Secs., Stroud, by Nov. 1.

BOILERS INSPECTOR, Huddersfield.—An inspector for the Huddersfield Steam Boiler Association who thoroughly understands steam engines and boilers. Salary £150 per annum. Application, with testimonials, to Mr. Daniel Cocking, Secretary, 13 Albert-buildings, New-street, Huddersfield.

ROLLER.—For rolling merchant iron, guide iron, and hoops. Apply to Mr. Hunt, Prince of Wales Iron Works, Millwall, Poplar, London.

LAWRIE AND HAGGER, Metal Broom
33 Lombard-street, E.C.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 14, 1859.

SCIENCE AND THE PRINCE CONSORT.

THERE are two features very strongly imprinted on the age in which we live. For one thing our time is marked by a very high development of humanity. We were greatly impressed by this in a recent visit to one of our public lunatic asylums. We entered a spacious, airy, handsome edifice, in the depth of a rural region, looking out on wood, meadow, and river. The physician in charge of the whole institution, a keen, cultivated, humane gentleman, and of an activity bright and incessant as a bird's, led us through all the wards, where we saw some six hundred insane persons. Numbers of them were peacefully employed, at washing, or cooking, or baking. None of them had any restraint on them beyond the eye of the attendant, and the walls of the building. All was cleanly and handsome that met their eye; their bed and board were of the wholesomest and best. The very lady of the house, the physician's wife, was just as devoted to these poor insane persons as he himself, — constantly amongst them, and expressing intimate affection for several of them; entertaining them with music on the Sunday, and in winter evenings getting up concerts and dramatic exhibitions for them. Altogether, the scene was a living symbol to us of our time, and made us feel afresh that the world has never before seen so high a development of humanity as that which meets the eyes of the present generation.

The other characteristic of our time to which we refer is its boldness, comprehensiveness, and certainty of mental inquiry, which expresses itself in its favourite term—science. We had a notable example of this in the speech of the Prince Consort at Aberdeen, which we reprinted in our journal a fortnight ago. It was a fine specimen of the best mind amongst us. What choice, pure English the language was, and of such delicate precision and beauty. What graceful personal modesty the speaker showed. How full the discourse was of the old German solidity and seriousness of purpose, that marks all the German people, whether in the old Fatherland or in Angleland. The term science in this address is made to embrace the whole range of the human mind. There are three objects of man's contemplation and inquiry—Nature, Man, God. The human mind has two methods of working—analysis and synthesis. It dissects into parts, observes, examines, reasons about each part; or intuitively it grasps the law that binds and controls the parts and knits them into a whole. All follow this method, says the Prince—the child, the man of mere practical instinct, or the philosopher. The child, as soon as his first surprise and ecstasy at the new universe subside a little, begins to ask the *how* and *why* of things. He practises his analysis by pulling his toy to pieces to discover how it works; or he performs a splendid generalisation; as, for example, when the fire burns him he affirms to himself that fire burns in every instance, at all places and times, though he has only experienced one instance of its burning power. The practical man is instinctively impelled to philosophise, in his rough, home-spun method, on the facts he is brought into contact with. But the philosopher, by stronger instinct and by conscious self-determination, directs his eye to every part of the great All.

Science, the Prince hints, has been of slow

growth in England, partly because we English are so wedded to what is immediately useful, what immediately shows a return in pounds, shillings, and pence; and partly from our excessive devotion to antiquity, that "till of late" has almost systematically excluded from our "school and university education" the great subjects and the results of modern inquiry, while it has given to antique things that liveliness of interest we feel all through life in the subjects we studied in early years.

The illustrious speaker lays great stress on the absence of all professionalism and officialism from science. Knowledge in his eyes has no aristocracy or priesthood. Its genuine students are not "a secret confraternity of men jealously guarding the mysteries of their profession"; their activity is "the republican activity of the Roman Forum." But if boldness and freedom, the Prince reminds us, are the characteristics of the philosopher, equally so is reverence. The more he explores the more he becomes aware of "the boundlessness of the universe, whose confines appear ever to retreat before our finite minds." True thinkers are "not conceited pedants, wrapped up in their own mysterious importance, but humble inquirers after truth; not God-defying Titans, but reverent, pious pilgrims towards a Holy Land—God's Truth"—God's laws, as manifested in His works, in "His creation."

Servility to mere rank as such we have supreme contempt for; but we confess to an unusual joy when a man in a high place has a higher light in him than those in low and even in high place around him; and such we conceive to be in this Prince's mind.

THE GREAT EASTERN.

THE trial trip of the Great Eastern has at last been made without accident, misadventure, or failure of any kind. By the untiring activity and exertion of the contractor, the injuries caused by the late explosion were so far repaired as to admit of the trip being entered upon on Saturday last. On reaching the ship on the morning of that day we were happy to observe that her condition was much improved in many ways. Sails were bent upon the yards and gaffs; the steering wheel was furnished with chains rove so as to increase the control of the steersman; the water-tight bulkheads were as sound and complete as was necessary; the staffs of the two engine-rooms and boiler departments were made up and well organized; the captain had a crew in whom he appeared to possess confidence; and altogether the ship presented a far more satisfactory aspect than on the occasion of the trip from the Thames to Portland. And this is a proper place for remarking that the materials and workmanship which have been supplied by Mr. Scott Russell throughout the equipment of the ship are of the very best kind—a circumstance which is not always observable in contract work. The firms to whom he committed the masting, rigging, and sail-fitting, for example, under sub-contracts, are among the most eminent in England—the Messrs. Ferguson and Co., Messrs. Westthorp and Co., Messrs. J. T. Hall and Co., and Messrs. J. and E. Wright—and we are enabled to state, on the authority of most of the heads of these firms, that Mr. Russell has rigidly enforced but one condition upon them, viz., that everything supplied should be of the very best kind manufactured by them. The masts and spars, standing rigging, running gear, and sails of the ship all attest the faithfulness of the sub-contractors to this condition, and reflect the highest credit upon Mr. Russell, the general contractor for the whole.

But notwithstanding the altered condition of things to which we have before alluded, it must not be understood that the state of the ship was unsuceptible of further improvement. On the contrary, we think the services of some of the sub-contractors—all of whom were notably ready to lend their aid at any sacrifice to themselves—might have been somewhat further continued with advantage. Had Mr. Hall had an opportunity of finally adjusting his sails to his own satisfaction their set would doubtless have been improved; and Mr. Westthorp's great experience in equipping vessels might have been further applied to equally good purpose; but, as we have on former occasions urged Captain Harrison to take the ship in his own hands, and as Mr. Scott Russell had strenuously pressed the Company to keep their engagements with the public by proceeding on the trial trip on the 8th inst., it would probably be unfair to charge the Captain with any remissness on these points. For this cause we also refrain from noticing some other matters which, to a certain extent, challenged criticism when we entered the ship on Saturday.

One of the most important and satisfactory consequences of the late explosion was visible in the absence of all water-heating cases around the funnels; these have been altogether done away with, the air now flowing freely through the space contained between the funnels and the casings. Thus, all accidents like the late one are rendered impossible in the ship for the future, although security has, of course, been gained at the expense of a certain amount of economy. The slight injury which the boiler sustained has also been repaired. This is so small a matter that it would not need another word but for the exaggerated importance which some writers for the newspapers have attached to it. These gentlemen tell us that the contractor is at issue with the Board of Trade Surveyor and the Directors of the Company on this point, the latter contending that the injured plate should be replaced by a new one, and the former that the repair has been properly made already by riveting a piece of plate over the injured part. We think the contractor is quite right. The word "patch" is all that alarms those who think otherwise—as if a riveted boiler itself is not a mere agglomeration of patches! No sensible man would think of unriveting a plate from a boiler, and causing all that weakness and liability to leak which may result from doing so, simply to repair a slight crack which does not even extend wholly through the metal, and which can be as effectually repaired by riveting a piece of plate over it. As to the remainder of the repairs which the explosion rendered necessary, it is sufficient to say they are fast approaching completion.

We come now to the trial trip; and at the outset would warn our readers against expecting too much, in the shape of data, from it, as regards either the speed of the ship or the economy of her boilers and engines. An ordinary ship must be subjected to many trials under various circumstances before final conclusions on these subjects can be arrived at; and in the case of the Great Eastern, which is an extraordinary ship in many respects, it will doubtless take a considerable time—perhaps a voyage or two across the seas—before her capabilities are properly understood. A deeper immersion, a different trim, an improvement in the form of the screw, an increase or decrease in the reefing of the paddle floats, greater experience on the part of the firemen and stokers—all these and some other things may tend to modify her speed hereafter. But whether a greater speed is ever to be attained or not, this

late trial trip was very satisfactory. For a short time on Sunday morning the speed predicted from the first by her builder—fifteen knots an hour—was attained. The fore and aft sails were set at the time, it is true; but the moderate breeze which was blowing could have added nothing to the speed derived from her engines, the only advantage of the sails being that of steadying the ship as she crossed the swell that beset her in her passage from the Scilly Islands to the Old Head of Kinsale in Ireland. When this speed was reached the screw engines made from 40 to 41, and the paddle from 11 to 12 revolutions per minute, the steam [boiler] pressure being about 22 lbs. We have no doubt whatever that if tried at the measured mile under moderately favourable circumstances it will be found that her speed will fall nothing short of the fifteen knots which she has already made.

There can be no question that this result is most satisfactory, and when the dimensions and horse-power of the ship are considered will be seen to surpass everything hitherto attained. The famous *Persia*, which is of but little more than one-sixth of the registered tonnage of the *Great Eastern*, and yet has more than one-third of her nominal power,* has made no more than fifteen knots, we believe, while in the tabulated lists of the Royal Navy† we find no vessel of anything like the same efficiency. The Admiralty there give us two formulæ by which they test the relative merits of steam-ships; the former involving the speed, midship section, and indicated power; the latter involving the weight instead of the midship section. To apply these tests to the *Great Eastern* we require of course to have her indicated power, midship section, and weight, and these we are able to supply with a sufficiently near approximation to the truth for our present purpose. Before leaving the ship we ascertained that the total indicated power, developed when the engines did their best, was about 7,200-horse power. We have further found by approximate calculations that with the draught of water with which the ship left Portland (25 feet aft, 21 feet forward, mean 23 feet) her midship section must have been about 1,600 square feet. Further, her weight must have been at least between 17,000 and 18,000 tons—say 17,500. We know that this must be near the weight, and at any rate cannot be in excess of it, because the mere iron in the hull weighs 8,000 tons, the engines and boilers about 2,000 tons (reckoning the weight three-fourths of a ton per nominal horse-power), and there were 6,000 tons of coals on board, in all 16,000 tons. To this we add 1,500 tons only for the weight of wood-work, masts, spars, and rigging, paddle wheels and screw, water in boilers, and everything else on board, which certainly cannot weigh less than that amount. Taking, then, these quantities—the speed 15 knots, the midship section 1,600 square feet, the displacement 17,500 tons—and substituting them in the two Admiralty formulæ successively, we get for the *Great Eastern's* characteristic numbers 750 and 316 respectively. Now, none of the Admiralty vessels reach such numbers as these. We have the *Agamemnon* giving 664, the *Miranda* 780, the *Tribune* 686, the *Algiers* 687, the *Simoom* 688, the *Desperate* 697, the *St. Jean D'Acre* 701, the *Princess Royal* nearly 725, and the *Cruiser* nearly 728, by the first formula; and we have the *St. Jean D'Acre* giving 201, the *Tribune* 202, the *Princess Royal* 203, the *Cruiser* 220, the *Desperate* 224, the *Simoom*

240, and the *Miranda* no less than 247 by the second formula; but the very best of these fall, as will be seen, considerably short of the *Great Eastern's* numbers in both cases.

Still, as we said before, we believe the *Great Eastern* will yet prove herself capable of more than she has hitherto accomplished. And we find reason for believing this in the results of a few experiments which were made off Holyhead on Monday before we entered the harbour. The ship was there tried first under paddles alone and then under the screw alone, and although the one propeller had in each case to drag or force the other through the water, speeds of no less than 8½ and nearly 9 knots respectively were attained. We watched these experiments very closely, carefully noting the periods at which the engines were stopped and the log cast, and whatever statements may have appeared elsewhere we assert, on our own carefully-acquired knowledge, that after the screw had stopped entirely for several minutes the paddles (driven by 1,000-horse power engines) propelled the huge vessel and dragged her screw at no less than 8½ knots, measured with the log by the ship's officers; and that when the paddles had nearly (but not altogether) come to rest the screw (driven by 1,600-horse power engines) propelled her at 9 knots. Now, if the screw had been properly immersed, it would have produced a considerably higher speed than the paddles, or should have done so, seeing that its engines were more powerful than the others by 60 per cent.; and there can be little doubt that when the ship is brought to a deeper draught of water aft, the screw will contrast less unfavourably with the paddles. It is only due, however, to Mr. Scott Russell to say that he took no part in bringing on the trials which terminated so favourably for his paddle-wheel engines; on the contrary, he objected to making them at all during the late trip, because time could not be afforded for disconnecting the paddles and the screw from their engines so as to give a fair opportunity for each propelling apparatus to display its full power; and in doing so he incurred the displeasure of some of the passengers—newspaper reporters and others—who of course understand such matters infinitely better than men like Messrs. Blake, Langdon, Scott Russell, and others. We are sorry to have to add that even Captain Harrison might with advantage have shown less disposition to interfere with such matters as the reefing of the paddle floats and other engineering points, in reference to which he evinces no unusual skill or knowledge. It is satisfactory, however, to know—and we state it from an intimate acquaintance with all the facts of the case—that Mr. Blake (the representative of the Boulton and Watt firm) and Mr. Russell, have maintained the most complete cordiality possible throughout the harassing transactions of the last few months. The engineers themselves being agreed on all points, it does not much matter whether people who know nothing of engineering think them right or wrong.

It is very gratifying to know that both the engines of the great ship work most admirably. Owing to a little looseness of the connecting rods upon the crank pin, the screw engines at present make more noise than is desirable, and if the defect were not remedied, would doubtless derange themselves prematurely; but a very little expense and trouble will suffice to make all as it should be in this respect. On Saturday evening, the escape valve of one of the paddle cylinders was held partially open for a few minutes by mud or sediment of some kind, but this was speedily removed without stopping the engines; and, on Monday afternoon, a similar thing occurred in one of the cylinders of the

screw engines, and made it necessary to stop them for a very few minutes. But for these occurrences, which were so insignificant as to deserve mentioning only for the sake of strict accuracy, it might have been said that both engines ran the whole forty-eight hours, from Portland to Kinsale, and thence to Holyhead, without ever stopping or manifesting the slightest tendency to derangement. This is a result upon which Messrs. Blake and Langdon (Boulton and Watt) and Mr. Scott Russell deserve the warmest congratulations. The paddle engines having, of course, a speed much inferior to that of the screw engines, doubtless offered a better chance of success to their constructor than the others, but they are nevertheless a marvel of mechanical construction. The four ponderous cylinders, each weighing with its piston and piston rod no less than thirty-eight tons, and moving with a stroke of fourteen feet, worked with a perfection which elicited continual admiration from the most experienced practical men on board the ship.

As to the sailing qualities of the *Great Eastern*, the trial trip showed absolutely nothing. Every scientific man must know perfectly well that when a ship is steaming at the rate of from fourteen to fifteen knots per hour with a moderate breeze considerably before the beam, no increase of speed can possibly result from hoisting fore and aft sails. By sheeting the sails well home, as was done on Sunday, you may, of course, find them of great service in steadying the ship, as we did; but even this effect is, to a great extent, due to the vessel's own motion through the air, which motion cannot, of course, be available as a source of speed. At the same time, there can be but little doubt that when put under an amount of sail proportionate to her size, the great ship will be second to none as a sailing craft. Her behaviour, so far as it has been observed, has given great satisfaction. As to her steering, it may be said that in running at full speed up the Irish Channel on Monday morning, her helm was put over seventeen degrees, and the ship turned through the complete circle in eighteen minutes. Through a deficiency of power in the steering apparatus, or rather in consequence of that apparatus not yet affording convenience for the application of sufficient power to it, the helm cannot at present be got hard over at full speed. The employment of a third steering wheel with the barrel prolonged to receive it will obviate this difficulty; and when this has been done, and the helm is capable of being put hard over at full speed, she will, of course, turn in much less time.

We were not able before leaving the ship to obtain unquestionable and detailed data respecting the consumption of fuel, &c., which we the less regret for reasons before stated. We may say, however, that the consumption of coal was said to have averaged from ninety to 100 tons per day in the paddle-engine boilers, and proportionately (to horse-power) in the screw-engine boilers, the average steam pressure being about eighteen pounds. The coal burnt was Hickson's Merthyr. On Monday morning the superheating steam apparatus was put into action in one of the boilers, and was found to raise the temperature of the steam from 246 degrees to 286.

Such are the principal facts which the trial trip of this wonderful ship has put us in possession of. Hereafter, we may be able to afford more detailed information. But, however that may be, we have only to consider carefully what has been already stated, and to supplement that by our knowledge of the general advantages which the great ship was designed to secure, and doubtless will secure, in order to see that

* The *Persia's* tonnage (registered) is 3,300; her horse-power 900. The *Great Eastern's* tonnage is 18,915; her total horse-power 2,600.

† Published in the Supplement of the *MECHANICS' MAGAZINE* for February 18, 1859.

in the Great Eastern her proprietors possess the most promising vessel in the world.

On another page will be found a detailed statement of the working of the paddle engines, with which we have been favoured the last time before going to press.

STEAM-SHIP ECONOMY.

In another portion of our impression for this week will be found a paper read by Mr. Charles Atherton, Chief Engineer at Her Majesty's Dockyard, Woolwich, at the last meeting of the British Association, on "Mercantile Steam Transport Economy as affected by the Consumption of Fuel." At the same meeting was presented a Report by the Committee appointed at the Leeds meeting, "On the best mode of recording facts of performances of vessels at sea under all circumstances." These and an interesting paper by Admiral Paris, of the Imperial French Navy, constituted the cream of the proceedings of section G at Aberdeen. And there cannot be a doubt that they all have reference to questions of the most interesting and important character that can be made the subject of discussion in a mercantile country. Our readers will remember that this is by no means the first time we have stepped forth into the arena to address ourselves to these and kindred subjects. It most unfortunately happened that our business formerly was to disembarrass the real questions at issue from the deadly embrace of crude and unsound theories of political economy in which they were tightly held. Mr. Atherton had, in fact, contrived to bring these questions before the British public in such a manner as to render their free and temperate discussion almost a matter of impossibility. Now, happily, the selfishness of the shipping interests, and frantic invocations of the Government and Parliament to take the shipowners' concerns under their paternal care, are no longer the order of the day; and the whole question of steam-ship performance is brought down to the sober, but perhaps less exciting region of calm philosophic inquiry, from which they had unfortunately soared on the back of Mr. Atherton's winged imagination. We congratulate that gentleman on the change that has passed over the spirit of his dream; and as our objections to his lucubrations have never been of a personal nature, but prompted by our anxiety that the interests of science should not be sacrificed by a false alliance, we willingly hail him as a friend while he consents to tread with us within the charmed circle of truthful and passionless inquiry.

To do the Committee of the British Association justice, they seem from the commencement to have recognised and adhered to the proper sphere of their action. Their first object, and a most important one truly, was to obtain experimental data of such a nature as should appear likely to promote improvement in the construction and performances of steam-vessels. Their action has been chiefly taken with a view to carry out this laudable design. They have applied to various quarters—the Admiralty among others—for information, suggesting a new form of return for trial performances, which they considered more complete than that now in use. Finding, by an examination of logs communicated to them, that the particulars given in them were very incomplete, they have drawn up another form of log which they propose for sea service, in which it seems they received very material service from Admiral Paris, whose valuable services as a corresponding member they early obtained. All this is so rational that, were it not for the somewhat different course adopted by a former committee, we should think it unnecessary to make special notice of

it. The Chairman of the Committee, Admiral Moorsom, has long been connected officially with the Chester and Holyhead Railway Company, whose boats perform the passenger service between Holyhead and Kingston; and he seems to have taken great pains to arrive at the best mode of ascertaining the performance of these vessels, and of securing due economy in their management. The most important and valuable returns are, as might naturally be expected, from this source, and are a tolerable indication of the nature of the information which the Committee have thought valuable. Economy and efficiency being the great objects aimed at in the management of these vessels, it may not be uninteresting to lay before our readers the details of these returns at some length. They consist of, 1, a return of the performances of the Chester and Holyhead Company's steam-vessels, *under a trial for a standard test*. 2. Return of the speed and consumption of fuel of the steamboats under regulated conditions of time, pressure, and expansion, for prior periods (1848 to 1850). 3. Return of the speed and consumption of coal of the *express* and *cargo* boats, under regulated conditions of time, pressure, and expansion, from January 31st, 1857, to December 31st, 1858. 4. Verification of consumption of coal from January 1st, 1857, to December 31st, 1858, to the introduction of a similar system into their own management. It is clear from what we have said that this Committee of the British Association has been doing good service, having been content to confine its operations to the business directly entrusted to it, and resisting the temptations to soar into more inviting but forbidden regions.

The contribution of Mr. Atherton is directed to ringing all the changes that can be got out of the combinations of the two formulas

$$C = \frac{V^2 D l}{\text{ind. h.p.}} \text{ and } C' = \frac{V^2 D l}{w}$$

in which C and C' are constants, V is the speed of the vessels in knots per hour, D is the displacement, and w is the weight of coal consumed per hour in cwts. We may state in a very few words the main objects which Mr. Atherton seeks in this paper. Assuming the consumption of coal to be 2½ lbs. per indicated horse-power per hour—which has been attained in a good model, but is considerably below what is usually attained in practice—assuming also the constant C from the formula

$$C = \frac{V^2 D l}{\text{ind. h.p.}}$$

to be 250, also deduced from a high type, he calculates the consumption of coal at 10 knots per hour for vessels of various sizes and horse-power from 250 tons displacement and 150 indicated, or 52 nominal horse-power, to 25,000 tons and 3,420 indicated, or 1,129 nominal horse-power. As in the performance of a voyage of definite length the consumption of coals varies as the square of the velocity, it is easy to reduce the consumption for any speed actually attained to that which it would be for 10 knots. The table constructed on this principle enables the persons interested to estimate the greater or less efficiency of any particular vessel by comparing the actual consumption of coals with what it ought to be according to this table—the efficiency, of course, being the greater for the less consumption, and *vice versa*.

Again, he constructs another table, assuming the same data for consumption of coals and index of dynamic performance, for vessels of various displacements, ranging from 1,000 to 25,000, and for the various speeds of 10, 15, 20, and 25 knots; the object now being to guide a constructor, presuming him to choose a type not inferior to the best, in adapting the size,

horse-power, and fuel in any vessel, for the service required to be performed of her.

Now, to all this we can cordially express our assent, and acknowledge that Mr. Atherton is doing good service by bringing home to the understanding of every one, and enabling him, as it were, to place his fingers upon what any purchaser of steam-power applied to marine locomotion may fairly and reasonably expect to obtain for his money, "being based on data *within the limits of actually realised results*." There are doubtless certain anomalies presented by most steam-ships to which these formulas have been applied to which we shall not now advert; but making due allowance for all these, we cannot but think that much will be gained towards mercantile transport economy—the efficient performance of any specified service at the minimum of cost and of wear and tear—by the diffusion of such knowledge as Mr. Atherton in this paper brings prominently forward.

The insufficiency, or rather gross inaccuracy and worthlessness of the present mode of estimating nominal horse-power, and the importance of some efficient mode of valuing the actual performance of a steam-ship, have not been confined to this side of the Channel. Admiral Paris, who has been mentioned several times in the course of our present notice, is the author of a pamphlet entitled, "Utilisation Economique des Navires a Vapeur," published in the course of last year at Paris. We can do little more than offer a mere outline of his remarks. The first half of his paper is devoted to the demolition of the present mode of valuing nominal horse-power, and proposing another in its place. From him we learn that there are seven different methods of calculating the nominal horse-power in the French navy—the main principle, however, being the same in all. From the number of cylinders, the diameter and length of strokes and number of strokes of the piston of each cylinder, it is easy to calculate the volume of steam used per minute or per second (the French, it appears, very frequently take the second for the unit of time, while we *always* employ the minute); to obtain the power there now only remains the element of steam pressure on the piston, which is always assumed both here and in France to be that given by Watt for the purpose of obtaining the nominal horse-power. Moreover, the number of strokes assumed in this calculation is also borrowed from the actual use of the early engines, and all marine engines work up to a power varying from three to four times that corresponding to the number obtained by such a process. The most important element of power is entirely omitted in this calculation, viz., the boiler with its heating surface and capability for production of steam. There can be no difficulty, then, in showing that all calculations based on this principle are delusive. The only question then is, what measure is to be substituted for this defective measure. In our country, by tacit consent, horse-power, as shown by the indicator—calculated, that is, from indicator diagrams—has practically superseded the nominal power. All theoretical tests of efficiency are referred to the indicated horse-power, it being assumed that in all well-constructed engines the loss of power through friction of the several parts of the engine, &c., falls within a certain per-centage varying within narrow limits, and that the work delivered at the working parts may be taken as bearing a fixed ratio to the whole work as shown by the indicator. To this, however, Admiral Paris demurs; he thinks the indicator too small and uncertain an instrument to place entire dependence on for so important a purpose. A little disorder in the spring would involve a considerable error in the calculated power; and

even were the working of the machine perfect, a very small error in the reading of the instrument would, in his judgment, introduce an error in the result too considerable to be overlooked. He proposes, therefore, to substitute for the indicator the mean pressure of the steam in the boiler, subject to certain conditions which we cannot now more particularly advert to. In the greater part of vessels he asserts that the mean pressure on the piston may be assumed to be one-half of the pressure in the boiler; and on this supposition a very ready and easy mode of calculating the horse-power is supplied. In any case, however, he proposes that the actual ratio of the pressure in the cylinder to that in the boiler may be tested by means of the indicator, and the indication of the horse-power thus rendered more reliable. He acknowledges that by making such an use of the indicator, viz., to obtain the ratio between the pressures, we seem to depend on the indicator almost, if not quite as much as when the power is calculated from the indicator alone, but he is of opinion that by using it only for the purpose of comparison we eliminate the greatest defects of the instrument. For our part, we are inclined to think that the two modes come pretty much to the same thing, and that the indicated power obtained as usual among us would not differ materially from the power calculated as proposed by Admiral Paris.

As, however, it is actual power which the purchaser of engines ought to pay for, it is agreed on both sides of the Channel that nominal power is no measure of what is the object of barter. Although, therefore, it is usual to pay for engines at the rate of so much per nominal horse-power, other conditions as to the actual working power of the engines are introduced into contracts which virtually set aside the nominal power as a measure of power to be obtained. We cannot see why the term and measure of nominal power should not be entirely discarded, and, instead, that the dimensions, &c., of the cylinders and pistons, and the dimensions of the boilers, including the area of fire-grates, &c., and the pressure at which the steam is to be generated, together with the indicated horse power to be developed under certain conditions, should not be the basis of the contract.

The second portion of the Admiral's pamphlet is very interesting, elucidating his "mode of appreciating the services rendered by the combustible, according to the magnitude of vessels." As captain of a steamer in the Imperial Navy, his attention seems to have been directed to the importance of discovering how to turn the power to the best service; and in this respect he approached the question from the same point of view as Admiral Moorsom. He was aware of the theoretical labours of M.M. Bourgois and Moll, and availed himself of them so far as suited his purpose. The formula on which he finally takes his stand is

$$C = \frac{V D I}{w},$$

when w is the weight of coal consumed. In France, in place of $\frac{1}{3}$ ds power of displacement, the area of midship section is generally employed. He gives at length his reasons for employing the former. Theory shows that the resistance is proportional to the midship section, which is a quantity of two dimensions. But, as in the comparison of different vessels the power of carrying cargo, which is measured by the displacement, is an important element, and as the displacement is a quantity of three dimensions, he adopts (Displacement) $^{\frac{1}{3}}$. We think, on the whole, the reasoning and the conclusion sound.

He introduces in his comparison an element, which is quite new to the English engi-

neer, viz., the main breadth of the vessel. He seems to have been led to adopt this because the line in his plan corresponding to the theoretical "utilisation" divided by the main breadth is nearly a vertical line, and offers some advantages as a kind of base line to which to refer the other lines which result from his treatment of his formula. The results he arrives at are not materially different from those with which our readers are familiar. The advantages of size in steam vessels are fully recognised, and amongst other remarks we are much struck with one which bears a close resemblance to one hazarded by ourselves some time ago in the pages of the MECHANICS' MAGAZINE, viz., that there is probably some definite velocity which is, as it were, natural to each vessel, up to which it works easily and beyond which it cannot be pushed without sacrifice of power. He enters somewhat at length into this speculation, and estimates the probable natural speed of the Great Eastern at about 20 or 21 knots per hour.

Neither our design nor our limits will permit us to discuss M. Paris's conclusions at more length. Our object has been mainly to show in what position the question of steam-ship economy now stands, and what progress has been made in establishing it on a sound basis. Enough has, we think, been said to illustrate the vast importance of the subject which is attracting attention in all directions, and to give hopes that the labours of the Committee of the British Association may conduce to valuable results, by interesting persons connected with the mercantile steam-marine in the subject, directing their attention to the proper objects of inquiry and observation, and at the same time, by showing how much their pecuniary success is involved in these inquiries, stimulating their zeal without alarming their fears by a threatened interference of the Legislature in their affairs, or wounding their pride by unnecessary and unwarrantable imputations of dishonesty and selfishness.

ANCIENT MODES OF COINING MONEY IN ENGLAND.

SINCE in our pages not long since an accurate and minute account of the process of coining as practiced at present in this country has been given, it may not be wrong to give through the same channel some information as to the ancient mode of money making. The usual gradations which almost all branches of manufacture in England have passed through in their advancement towards perfection are quite traceable in the manufacture of money. Originally the heaviest operations in connection with the coinage were performed by manual labour; afterwards by the power of water, or of horses, and finally by the irresistible force of steam. To inquire into and explain the oldest system of coining, and to note the "gradual steps and slow" by which the newest improvement in the art was attained, will now be our task.

From the earliest records extant in the kingdom bearing upon the subject, we gain some curious information touching the methods of coining pursued in the infancy of our existence as a civilised nation; but there is an amount of vagueness about these documents which was evidently intended by the writers to hedge in the subject by difficulty and doubt. It is plain, however, from their moth-eaten and musty testimony—rendered from their niches in the State Paper Office, and in the British Museum—that in the early Saxon and Norman times there were a variety of small Mints established in various parts of the country, and in some cases two or three in the same city or town. These petty places for the manufacture of current coin were either under the direct supervision of the king, of some favourite prelate, or of a subject whom his majesty delighted to honour. Each of

these, too, was managed and governed by a single Master or Minter, responsible for the character of the coins produced, and guaranteeing their genuineness by stamping upon each piece the initials of his name.

It is evident, that although the operation of money-making in those primitive days was one of the most simple that could be conceived—as we should think—yet that a great amount of secrecy was observed by all concerned in carrying it on. Frequently in the old parchments better-named, the term "mystery of the Mint" occurs in connection with it, and there palpably existed in the minds both of legislators and minters a wholesome and profound horror of counterfeit coins and "smashers." In each of the kingdoms of the Saxon Heptarchy there was established at least one of these mints; and from written evidence, confirmed most completely by that borne on the faces of coins yet happily preserved, it is evident that the mechanical appliances of those establishments were of the most limited number and rudest character. In fact, it is not going beyond the truth to say that there exist in England at this hour numerous private mints for the manipulation of counterfeits, whose general fittings are not dissimilar to the Royal mints of the ancient kingdoms of the Saxon Heptarchy! and which have the advantage of superior artists and better workmen to assist their proprietors.

The earliest specimens of coins of English manufacture were palpably the direct produce of the melting pot and the mould. Clay or chalk moulds, with the device intended to ornament the money, cut in *intaglio* upon them, were prepared. Then a cylindrical vessel in which charcoal might be used as fuel, and forming a miniature smelting furnace, was provided, and these with a few inflexible "pipkins" for crucibles to hold the metals, a pair or two of tongs, a file, or cutting tool of some kind, and scales for weighing of the monies, constituted unquestionably all the machinery of each of their Majesties' mints of the year 900! The well-known "man and a boy" would have been an almost competent staff for working one of these little "money-making concerns," at any rate two men and a boy would have been ample. In those days of limited—very limited—cash payments, and when competition among small traders was very small, the number of coins thus produced in ten hours would be doubtless sufficient for the diurnal requirements made upon each mint. It is thought likely that in the time of Athelstan this melting and pouring system was superseded by another, which if it had not involved the use of engraved metallic tools, or dies, would have been nearly as simple. The melted bullion was now poured through a sieve—as in the modern plan of casting small shot—and the resulting globules of metal—some of which in the form of flattened hemispheres still exist—having been placed on a stone and struck by a stamp with force of hammer, then received a blow that, serving to flatten and to impress their upper sides with the device engraved on the die, prepared them also for the active duties of circulation. Although the use of iron or steel stamps incident to this latter arrangement occasioned the employment additionally of a blacksmith and die engraver, yet the personal establishment required to carry it on practically remained as limited as in the "pot and mould" system.

The "hammer and die" method of coining existed for a considerable time, and the coins resulting from it exhibit a sharpness of finish which neither the coiners of the Heptarchy a thousand years since nor those of Whitechapel or Birmingham of to-day are able to produce on cast pieces of money. In the museum of the Tower-hill Mint there are, as we are informed, preserved several of the blacksmith-like tools or dies which were used in the process last referred to, and even collars of lead with which the workmen held them whilst being struck, in order to prevent the jarring caused by the blow from being transmitted to their own muscular systems. This mode of coining, however, was attended with several draw-

backs, and the march of improvement, then a very slow march, caused at length its abandonment. The frequently-recurring series of meltings required, attended as they were by expense and loss of time, was one of the most serious of these drawbacks. It is unfortunate that the names of the ingenious individuals who suggested and perfected, no doubt after much thought and experimentation, the plan which immediately succeeded the globe system, are lost in the mists of antiquity. But that plan is worthy of especial note. Cylindrical ingots were cast of considerable length and of the exact diameters of the coins to be produced; and these when cut transversely yielded, of course, discs of metal of nearly the proper thickness. The file and scales were the means of bringing them to the exact weight required, and nothing remained but to place them one by one upon an engraved die, and then administer to another die held carefully upon the piece a sharp blow with a hammer. This system is employed, we believe, at some of the Indian mints—those not under British control—up to this hour, and it cannot be denied that it is not a bad system. Indeed, with the mechanical appliances which might now be brought to bear in carrying out such an arrangement, it is by no means certain that it might not be economically and effectively carried on at home. It does not seem an irrational idea to cast bars of metal, in well-finished cylindrical moulds,—of steel or even of cast iron—of the precise diameter of each denomination of coin, and then by the rapid action of machines to cut, in the fashion of a cucumber slicer, discs of metal of the proper thickness to give each a proper weight. The melting pot would thus perform a principal part of the operation of coining, and the rolling mills would be dispensed with entirely! As it is, in most mints, rectangular bars are cast, and these have to be elongated by lamination, brought by gauge to the right thickness, and then perforated by circular punches of the sizes of the various coins. Necessarily a great proportion, it is said nearly half—and it must be so—of the metal issued from the melting department must by this mode go back to it for reconversion into new bars. By the cylindrical process it is clear that a very small portion of a batch of well-cast bars would require remelting. The moulds might, in the present advanced state of mechanical science, be made as smooth within as the inside of a musket barrel, and thus perfectly "clean" castings would be obtained from them, whilst the slicing machines would at once feed the bars forward and shear them off in blanks of the thickness for florins, shillings, or any other coin, and which the stamping presses would finish most rapidly for issue. But without pursuing this digression further, we return to the history of the rise and progress of coining.

From the Red Book of the Exchequer, quoted by Leake and referred to by Ruding, it appears that the new money struck in the eighteenth year of the reign of Edward I. was made in the following manner:—First, the metal was cast from the melting-pot into long rectangular bars; these bars were cut by shears into square pieces of exact weights; then with tongs and hammer they were forged into round shape; after which they were blanched, that is, made clean and soft by annealing and boiling in acid, and then stamped or impressed by being placed as described between dies, and thus made current coin. The advantage of this change is not very apparent, for it involves a great deal of additional labour, without any proportionate advantage. But at any rate the plan appeared to have remained in force until the year 1581. Queen Mary, however, caused an important change to be made, prior to that date—about 1546, indeed—as regarded the localities in which minting was carried on. Her popish majesty consolidated the Royal mints of the kingdom under one roof, and the provincial mints, as a matter of course, were all closed. In the Tower of London all the monies produced in her reign were coined.

The year 1561 was the epoch of a remarkable improvement in the mode of manipulating money. A Frenchman then introduced the "mill and

screw" for the first time in the English mint. This system was found to work well, but it is said to state that the French inventor who was the means of its introduction was hanged at Tyburn for counterfeiting! Not satisfied with the means of making money for the Government, he established a private mint, and was accordingly made a public example of at that terrible place of retribution. Whether the use of his machinery was ever entirely discontinued does not clearly appear, but it is quite certain, from the evidence of coin subsequently struck, and some of which is still extant, that up to the middle of the next century the hammer was used for getting up impressions. In 1629 a Royal warrant was issued authorising Nicholas Briot, the eminent engraver to the mint at that time, to make trial in the Tower of his new method of coining money by mills and presses; but from certain impediments put in his way by the executive officers of the place this trial was set aside. In 1649 "the Council of State and Commons in Parliament" having had it represented to them that the coins of the Government might be more perfectly and beautifully done, the Council of State therefore ordained, on the 8th of August, to send for Peter Blondeau from Paris to come to London to treat with them upon the price and expense of coining money after his new invention. He accordingly arrived in town on the 3rd of September following, but though a committee of the Mint was appointed to examine into his new way of coining, and a very favourable report was made respecting it, yet so powerful was the opposition of certain "moneyers," who appear to have somehow had a vested interest in keeping things as they were, that a very considerable time elapsed before a trial of it was made. Blondeau at last nevertheless succeeded in executing some proof-pieces, but his enemies produced against them other proof pieces, and instituted into the bargain a prosecution against the French machinist for coining money in a private house. Their continued opposition at length drove Blondeau back to Paris.

Before finally passing from this period it may be said that from the excellence of the engraving of Briot and Simon, it developed very great beauty and perfection in the coinage. Indeed, notwithstanding the more recent employment of comparatively magnificent machinery to any then in use, with elaborate arrangements, appliances of every kind, and notwithstanding the increase of salaries to officers of the Mint, amounting in the aggregate to £10,000 or £12,000, against a total then paid of £650, still scarcely an approach has since been made to the excellence of the coins they executed. When it is taken into account, also, that the inferiority of the coinage, as regards execution, is the main source of the facility of counterfeiting, and of the correlative heavy law expenses of prosecuting offenders of the coin laws, that becomes rather an important admission. From the time of Simon, the engraver, it is certain the coinage has of the two degenerated. In the time of William III. this fact was publicly announced, for in a State document of his reign we read that "our present money is so disingenuously coined, that it may be easily debased, diminished, and counterfeited."

In 1662 Blondeau triumphed over the banded opposition which had caused his disappearance from the country, and agreements were entered into with him to "furnish all the mills, rollers, presses, &c., &c., necessary, and to instruct the moneyers in the use of his newly-invented tools and engines." The moneyers were bound to pass the plates of gold or silver through the *horse* mill, and to cut, flatten, size, neale, blanch, and coin the pieces; to maintain the *horses*, to find alum, argot, and sawdust, to keep in repair the ovens, furnaces, and utensils for nealing and blanching; to make good the balances, small files, tube, trays, bowls, and sacks, and all waste of gold and silver in nealing, blanching, and working. This was, therefore, the *horse* stage in the history of the coinage. With certain modifications of details the principles of Blondeau's plans of coining were successfully acted upon until the intro-

duction in 1810 of Boulton and Watt's powerful steam machinery, which, with sundry additions, is now employed on Tower-hill for the manipulation of coins, and has been heretofore described by us.

It appears that from the very earliest period of the annals of coining in this country counterfeiters have successfully plied their craft; but it seems that about 1560-61 the crime was at its height. At that time a great re-coinage took place, and it is on record that of 631,950 pounds of money then re-coined only 244,416 pounds of "fine monies" could be produced, whilst the dross of this mass of metals was "carried to foul highways" and places where rubbish might be shot. In fact, the bulk of waste in this re-coinage must have been considerable, as the difference of weight after the metal had been reduced to standard was 387,534 pounds. A strange story is told, too, of the workmen engaged in melting down the base coins; "most of them," it is said, "fell sick to death with the savour, and were advised to drink in a dead man's skull for their cure, and, accordingly, a warrant was procured from the Council to take off the heads from London-bridge and to make cups of them, out of which they drunk and found some relief, (?) although most of them died." It is probable that the sickness arose from their inhalation of the fumes of arsenic with which the base metal was mixed, but it is very questionable whether the medical prescription was a good one.

There are other interesting particulars in connection with the progress of minting, and it is not unlikely that at an early opportunity we may recur to the subject.

STEAM SHIP ECONOMY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I beg to forward herewith a copy of the paper presented by me to the British Association at their late meeting at Aberdeen, in continuation of my former papers on "Mercantile Steam Transport Economy." The public import of this paper will, I hope, induce you to give it the extensive publicity which is afforded by the MECHANICS' MAGAZINE. I have endeavoured to make the papers explicit, but as the study of such subjects requires considerable time and attention, it may not be amiss that I somewhat prepare your readers for it with the remark, that the object of the paper is to popularise some method of determining the relative dynamic merits of steamers as implements of transport, by comparing the coal duty actually performed by them with the coal duty capable of being performed by ships of a certain definite scale of efficiency taken as a standard of comparison. If one steam-ship be inferior to another as respects its capability for performing transport duty, that is, the ratio of work performed to coals consumed, there must be some cause, or combination of causes, for such difference; but the fact of inferiority being established, the cause will be inquired into, and it will soon be ascertained whether the fault lie in the condition or type of form of the hull, or with the condition, construction, or management of the boilers and machinery. It is evident that however excellent the type of form of a ship may be, a foul bottom will (*ceteris paribus*) detract from its speed; the best coals may be consumed by badly stoked or badly constructed boilers without producing their due amount of steam, and from the bad adaptation or bad management of engines, an undue proportion of the indicated power may be non-effective. Abuse in any one of these points will tell its tale when the coal duty of a steam-ship comes to be compared with that of a standard type; under such a system of comparison one ship with another, it may be expected that steam

shipping improvement, as respects construction and management, will be gradually advanced, and, consequently, that mercantile steam transport economy will be gradually promoted, to the benefit of public interests. I am, Gentlemen,

Your very obedient servant,

CHARLES ATHERTON.

Woolwich Dockyard, 6th Sept., 1859.

MERCANTILE STEAM TRANSPORT ECONOMY AS AFFECTED BY THE CONSUMPTION OF FUEL.

By CHARLES ATHERTON, Chief Engineer, Royal Dockyard, Woolwich.

Public usefulness, as dependent upon science, being the great object for which the "British Association for the Advancement of Science" was originated, and has now been signally upheld for 29 years, a period remarkable for the progress that has been made in the utilisation of the powers of nature to such extent that the international condition of the globe is now being revolutionised by the progressive practical utilisation of elements which heretofore were regarded merely as phenomena of nature, viz., steam and electricity; in which revolution the application of steam to the purposes of navigation has played so conspicuous a part, that now, in proportion as steam may be effectively employed in the pursuits of commerce and of war, it is acknowledged that even nations will rise and fall. Seeing, moreover, that at no

period in the history of steam navigation has so great a step been made in its practical development as may now be said to have been realised by the fearless introduction, in marine engineering, of the long-known and well-understood effects of increased pressure, superheating, and expansion; the recognition and application of which principles has now, at length, been attended with such effect in marine engineering, that the consumption of fuel with reference to power is now shown to be practically reducible to less than one-half of the ordinary consumption on board ship. Seeing, also, that mercantile enterprise, setting no limits to speculative investments, has in these days emancipated mechanical intellect from the fetters by which ideas as respects magnitude have hitherto been bound. Under such circumstances I cannot doubt that any effort to popularise a knowledge of the practical utilisation of steam, with reference to the consumption of fuel, though advanced with no pretensions to science, beyond that which may be awarded to originality and labour in the application of calculations to developing useful results, will be favourably received; more especially as the paper which I now beg to present is in continuation and conclusion of an inquiry which has already, in part, on two occasions, been favourably entertained by this Association, and honoured with a place in its published records. The former papers to which I allude are:—1st. "Mercantile Steam Transport Economy with reference to Speed."—Vol. for 1856. p. 428. 2nd. "Mercantile Steam Transport Economy, with reference to the Magnitude of Ships, and their Proportions of Build."—Vol. for 1857, p. 112. And I now purpose to bring this inquiry to its conclusion by the following paper on

Mercantile Steam Transport Economy, as affected by the Consumption of Coals.

My purpose, and the drift of my remarks, will, probably, be the more readily understood by my at once adducing the following tables C and D, and the diagram E, in continuation of the tables A and B, which are published in the Volume of Transactions for the year 1857, pp. 116 and 119, observing with reference to these tables C and D, that the rate of consumption of coal on which the calculations are based, viz., 24 lbs. per indicated

horse power per hour has been practically realised on continuous sea-service, although the ordinary consumption of steam-ships in the Royal Navy, as well as in the best vessels of the most celebrated steam shipping companies, is, I believe, at the present time, fully 50 per cent. in excess of that amount; and I may say, that in steam ships generally, the consumption of coals per knot of distance, with reference to displacement and speed, is double the consumption which these tables, based as they are on an example of existing practice, show to be now practically realisable.

The tables now adduced are as follows:—

Table C, calculated for the speed of 10 knots per hour, showing the mutual relations of displacement, power, and the consumption of coals per day, per hour, and per knot, for vessels of a gradation of sizes, from 250 tons displacement up to 25,000 tons, the co-efficient of dynamic performance, deduced from the formula $\frac{V^3 D^{\frac{1}{2}}}{\text{ind. h.p.}}$ being assumed to be 250, and the consumption of coals being assumed to be at the rate of 24 lbs. per indicated h. p. per hour. On these data, the co-efficient with reference to coals deduced from the formula $\frac{V^3 D^{\frac{1}{2}}}{\text{ind. h.p.}}$ (w being the consumption of

coals per hour expressed in cwts.) becomes 11.210.

Table D, showing the mutual relation of displacement, power, and coals consumed per day, per hour, and per knot, for the respective speeds of 10, 15, 20, and 25 knots per hour. The data on which this table is calculated being the same as above described for Table C.

Diagram E, showing approximately by scale the nautical mileage consumption of coals for vessels from 1,000 tons displacement up to 25,000 tons, deduced from Table D.

It will be observed that in Table C the tabulated sizes of ships, as determined by their respective load displacements, increase progressively from 250 tons displacement up to 25,000 tons, showing under assumed conditions, which, however, are justified by the present circumstances of realised advancement in steam navigation, the mutual relations of displacement and coals calculated for the speed of 10 knots per hour as most convenient for a standard of reference. The in-

TABLE C.
Calculated for the Speed of 10 knots per hour, and showing the mutual relations of Displacement, Power, and the Consumption of Coals, per Day, Hour, and Knot, the Co-efficient of Dynamic Performance, deduced from the Formula $\frac{V^3 D^{\frac{1}{2}}}{\text{ind. h.p.}}$ being assumed to be 250, and the consumption of fuel at the rate of 24 lbs. per ind. h.p. per hour.

DISPLACEMENT.	Nominal H.P. taken at the unit 100,000 lbs. 1 ft. per min.	Indicated H.P. taken at the unit 33,000 lbs. 1 ft. per min.	COALS.

TABLE D.
Showing the Mutual Relations of Displacement, Power, and Coals consumed per Day, per Hour, and per Knot, for the respective Speeds of 10, 15, 20, and 25 Knots per Hour. The Co-efficient of Dynamic Performance being deduced from the Formula $\frac{V^3 D^{\frac{1}{2}}}{\text{ind. h.p.}}$ being assumed to be 250, and the Consumption of Coals being assumed to be at the rate of 24 lbs. per indicated horse power per hour.

Displacement in Tons weight, at 35 cubic ft. of Sea Water per Ton.	10 Knots.						15 Knots.						20 Knots.						25 Knots.

ned practical use of this Table C is to facilitate mercantile investigation into the dynamic merits of steam-ships as locomotive implements of bur-
m by comparing their actual consumption of fuel with the calculated consumption of the ship of corresponding size and speed as recorded in this tabulated standard of comparison, whence the constructive merit of ships, as respects their *work-
g economy of fuel, on which the cost of freight so
uch depends*, may be relatively ascertained. For
ample, a certain ship of 800 tons mean dis-
placement attains the speed of 8.8 knots per
hour, with a consumption of coals certainly not
ceeding 4.3 cwts. per hour, or 49 cwts. per
autical mile or knot; which (as the consumption
coals per knot varies *ceteris paribus* as the
uare of the speed) is equivalent to 63 cwts. per
ot at the speed of 10 knots per hour. Now, by
ferring to Table C we find that on the assumed
a therein referred to the standard ship of 800
ns displacement, steaming at 10 knots per hour,
ould consume 77 cwts. of coal per knot. Hence,
efore, it appears that the ship referred to in
is instance is *superior* to the tabulated standard
the proportion of .77 to .63, that is, in the pro-
ortion of 122 to 100, the superiority with refer-
ce to the consumption of coals per knot being
per cent.

Again, a certain ship of 8,500 tons mean sea
placement makes a voyage at the average speed
12.88 knots per hour, consuming 33 cwts. of

coal per hour, or 6.44 cwts. per knot, which, by
the law of dynamics above quoted, is equivalent
to 3.88 cwts. per knot at the speed of 10 knots per
hour; but by referring to the Table of comparison
C, we find that the standard ship of 3,500 tons
displacement, steaming at 10 knots per hour,
would consume only 2.06 cwts. of coal per knot.
Hence, therefore, it appears that the ship referred
to in this instance is *inferior* to the tabulated
standard ship in the proportion of 3.88 to 2.06,
that is, in the proportion of 63 to 100, the infe-
riority with reference to the consumption of coals
being 47 per cent.

Thus, by reference to this tabulated standard of
comparison (C), we have the means of readily de-
ducing the exact per-centage by which ships, as
respects the dynamic duty performed with refer-
ence to the consumption of coals, differ from each
other. I need not dwell on the importance of
this consideration as affecting the commercial
value of ships.

With reference to Table D, showing the mutual
relations of displacement, power, and coals con-
sumed per day, per hour, and per knot for the
respective speeds of 10, 15, 20, and 25 knots per
hour, the object of this table is to show the ex-
tent to which the required engine-power and the
nautical mileage consumption of coals are depend-
ent on the rate of speed, thereby facilitating the
adaptation of ships as respects their size and
power to the service that may be required of them.

It be purposed that the steaming speed shall be at
the rate of 15 knots per hour, the required power,
as appears by Table D, will be 3,947 ind. h. p.,
consequently the weight of the engines will be
395 tons and the maximum displacement avail-
able for coals will be 5,000—2,395=2,605 tons
weight, or 52,100 cwt., which, at the tabulated
rate of consumption, 5.87 cwts. per knot, would
be sufficient only for a passage of 8,876 nautical
miles, and this to the utter exclusion of all goods
cargo, showing that the ship is inadequate for
steaming 12,000 nautical miles at the required
speed of 15 knots per hour, though the same ship,
if duly fitted with engine-power for steaming at
10 knots per hour, would perform the whole
passage of 12,000 nautical miles without re-
coaling at any intermediate station, and carry 1,317
tons of re-storing goods cargo.

These few examples will, it is hoped, sufficiently
illustrate the application and use of Tables C and
D in facilitating mercantile inquiry into the
capabilities of steam-ships with reference to the
all-important question of consumption of coals;
but in order still further to facilitate calculations
on this subject, the Diagram E has been prepared,
whence, simply by inspection, the consumption of
coals per knot, at any rate of speed, may be
approximately ascertained for vessels from 1,000
tons displacement up to 25,000 tons, the data on
which this diagram has been calculated being the
same as that on which Tables C and D are based.

The use and application of this Diagram E is
evident; it brings the tables under ocular review,
and generalises their application. It is given as
an example of a system that admits of being more
fully and elaborately developed for the purposes of
mercantile tabular reference, as is now being done
for publication.

Having thus explained the use and application
of Tables C and D and the Diagram E, it will be
perceived that the task which I have undertaken
on this occasion is to show palpably by comparison
with these tabular statements, *based on data with-
in the limits of already realised results*, taken as
a standard, what is the character of steam-ships
as respects their locomotive or dynamic capabilities,
with reference to the economic performance of
mercantile transport service, so far as dependent on
the consumption of fuel, thus affording an exposi-
tion whereby parties interested in steam shipping,
either as owners or directors, or agents, or as the
charterers of shipping for Government or for
private service, though unacquainted with the
details of marine engineering as a science, may be
enabled to arrive at some definite appreciation of
the amount of work that may be expected of
steamers; that is, the weight of cargo they will
carry, and the length of passage capable of being
performed at any definite speed, for, as before
observed, the dead weight of cargo that a ship
will carry is equal to the tons' weight of water
displaced between the light and load water-
lines of the ship, less the weight of coals re-
quired for the voyage, and which for long
voyages commonly amounts to four times the
weight of cargo chargeable as freight, and it
constitutes the limitation of distance which the
ship is able to run under steam at a given speed.
This inquiry is therefore essential to a due ap-
preciation of the economic consequences which
are involved in progressive variations of steam-
ship speed, especially as respects the high rates of
speed, which are occasionally professed, but which
are seldom realised, simply because there has been
no recognised exposition whereby such preten-
sions may be judged of with reference to the
required consumption of fuel. In short, regarding
this matter as a public cause, affecting as it does
the pecuniary interest of the public to the extent
of millions sterling per annum, my object is to
promulgate, through the medium of the
notoriety which every inquiry obtains upon its
being brought before the notice of the
"British Association for the Advancement
of Science," a Mercantile Steam-Ship Ex-
positor, by reference to which as a standard of
comparison the good or bad qualities of steam
shipping may be determined; and this work

Diagram showing approximately the Nautical Mileage Consumption of Fuel, Vessels from 1,000 tons displacement, up to 25,000 tons, the Co-efficients of dynamic Performance deduced from the Formula $V^3 \propto D^{\frac{2}{3}}$ being assumed to be constant, and the Consumption of Coals being assumed to be at the rate of $2\frac{1}{2}$ lbs. per Ind. H. P. per hour.

For example, by refer-
ring to Table D, we ob-
serve that a ship of 5,000
tons displacement, steam-
ing at 10 knots per hour,
requires 1,170 indicated
h. p., and consumes 2.61
cwts. of coal per knot;
but to steam 15 knots
per hour, the same vessel
would require 3,947 ind.
h. p., and the consump-
tion of coals would be
5.87 cwts. per knot; hence
it appears that to in-
crease the speed from 10
knots to 15 knots per hour,
the power requires to be
increased upwards of
three times, and the con-
sumption of coals per knot
is more than doubled.

Again, let it be supposed
that the weight of the hull
of a ship of 5,000 tons
displacement fitted for
sea amounts to 40 per
cent. of the displacement,
or 2,000 tons, and sup-
pose the weight of the
engines and boilers to
be one ton for each 10
indicated h. p., the vessel
requiring, as shown by
Table D, 1,170 indicated
h. p., to attain the speed
of 10 knots per hour, with
a consumption of coals at
the rate of 2.61 cwts. per
knot, then on these data,
the engines, to attain the
speed of 10 knots per
hour, would weigh 117
tons, and the weight of
coals for a passage of,
say 12,000 nautical miles,
would be $12,000 \times 2.61 =$
 $31,320$ cwts., or 1,566
tons weight, making
together for hull, en-
gines, and coals, $2,000 +$
 $117 + 1,566 = 3,683$, and
consequently the displace-
ment available for cargo
would be $5,000 - 3,683 =$
 $1,317$ tons weight. But if

HEINKE'S PATENT DIVING APPARATUS.

is a public cause, for by the operation of the scrutiny which such a system of comparative exposition may be expected to inaugurate and popularise, steamers will soon become marketable, with reference, in great measure, to their capabilities for economic transport service, according to the speed that may be required; and under the influence of this scrutiny all bad types of form and vicious adaptation of mechanical system, will be eradicated; incompetency in steam-ship management will become gradually eliminated, and the mercantile transport service of the country being then performed exclusively by good, well-appointed, and well-managed ships, would be performed at a minimum of cost to the shipping interests, and consequently to the best advantage for the interests of the public. Hitherto the dynamic character of steam-ships has been a mechanical problem enveloped in undefined and even delusive terms of shipping and engineering art; consequently, its determination has not been based on any recognised principles of calculation. Hence the dynamical character of shipping has been a mystery—a matter of mere assertion on the one hand, and of credulity on the other. But mystery being unveiled, commercial vision will be opened, and competition, in shipping as in any other well-understood and open field of public enterprise, will insure the mercantile transport service of the country being performed to the best advantage, and it will gradually establish and preserve the just equilibrium of trade as between the carriers and consumers of all the sea-borne productions of the earth.

CHAS. ATHERTON.

Woolwich Dockyard, 1st Sept., 1859.

HEINKE'S PATENT SUBMARINE DIVING APPARATUS.

A safe and efficient apparatus to enable operations to be conducted under water has long been considered a very important and desirable object of attainment. Mr. Heinke, who is well known as an engineer who has spent the best part of his time of late years in submarine operations, has recently patented a new apparatus which combines so many improvements that we have much pleasure in introducing it to our readers. It consists of a diving helmet, which is attached to a waterproof dress, and a submarine lamp, which forms a most useful adjunct. We will first describe the helmet. Upon the breast-plate of this helmet, and in front of the diver, is placed a safety valve, so as to be easy of access, which at any moment he

can close partially or wholly, so as to regulate the egress of the air fed down from above. If he shuts this valve completely, his waterproof dress is at once inflated, and his buoyancy becomes so great that without any effort he rises to the surface like a cork, in a much more expeditious manner than he could climb up by the ladder, or even be drawn up by those stationed above. If at any time part of his dress should become injured, or the glasses before his eyes be broken, the opening thus formed can in an instant (by closing the valve) be turned into the egress hole, and the air made to take that course, to the total exclusion of the water. The value of this improvement has been well exemplified in the course of the work upon the new Westminster Bridge, where Heinke's apparatus is exclusively used; for in one instance a diver struck one of his glasses against a spike, and if he had not closed his valve, water would instantly have been admitted, and, doubtless, he would have been drowned; but, as it was, he turned the valve, and felt no inconvenience, nor were his clothes even moistened by the accident. We subjoin a woodcut showing a section and ele-

vation of one of Heinke's helmets, as also a sectional view of the valve. Fig. 1 shows a front elevation of the helmet itself. It will be seen from this that the openings are also provided (as an extra safety-guard) with segmental plates, so that by turning either disc round by means of the buttons which project from the circumference, the openings can be closed instantaneously. The regulating or safety valve is seen in front of the helmet, just below the joint indicated by the letter A, which joint enables the whole top of the helmet to be taken off at pleasure. Fig. 2 shows a section through the head-piece, exhibiting the pipe at the back through which the air is fed down the valve for safety in the event of the bursting of a feed-pipe. From the orifice will be seen the tubes, extending over the upper internal surface of the helmet, for leading the stream of air over the glasses; and again below, and marked by the letter B, will be seen the safety valve before-mentioned, which can be opened or shut at pleasure by the diver. This valve is shown in section on a larger scale in Fig. 3. It will there be seen that an ordinary valve, which is held in place upon its seat by means of a spiral spring, is covered with a cap perforated on the top, so as to allow of the escape of such air as passes, but so fitted as to turn upon the outside of the valve-box or seat at pleasure; this is provided with a long slotted hole, which runs some distance around its circumference, and the lower part of the valve-seat or box is provided with a similar slot. From this description it will be apparent that the cap can be turned so as either to let the two holes be in one, and thus open to allow of the escape of the air, or be closed, should it be desired; by this simple contrivance the diver can regulate the egress of the air, and so the extent of the supply to the greatest nicety. We must now pass on to the latest of Mr. Heinke's improvements, that of his lamp. Figs. 4 and 5 show a side elevation and longitudinal section of this lamp, which, it will be noticed, possesses the following peculiarities and advantages. The amount of air which is supplied through the pipe A, Fig. 4, can be regulated by means of the tap; the air thus admitted flows into the external ring or case, which is shown by the letters B B in the sectional elevation, Fig. 5; it then finds its way through the perforated plate C C, at the bottom of the ring, into the receptacle D D, and thence through the strainer E into the lamp itself, for the support of combustion. The burner itself is of the form commonly called argand, and supplied with oil or gas for a

g F, which is made open, so as to allow of it from the lamp being thrown down from the top of the vessel, through the lense H, so that by means the bottom surface of the sea can be seen without removing the lamp from its position. The lamp is also provided with the lenses I I; or three can be used if required.

The upper cap is fitted with an internal which is connected with a pipe leading to the surface of the water for the escape of the products of combustion. This lamp gives a brilliant and the air supplied percolating through the water ring enables it to burn steadily, a of considerable importance in such cases. We have now described in detail an apparatus of which a man may in comparative safety descend to his labour at the bottom of the sea on all ships, and in fact all others, but more especially screw vessels, if furnished with an apparatus of this sort, would be provided with means of investigating the causes of leak, and, in many instances, of counteracting accidental effects without the waste of time which arises from returning to port.

Seeing as Mr. Heinke's apparatus does so many advantages, it is not to be wondered that it is being every day more extensively used. The *Times* of the 10th inst. will have noticed that it has been employed upon many large works, and, at others, in removing the foundations of a bridge at Rochester; in this instance of the officers of the Royal Engineers were ordered to descend in one of the dresses, and did not, they tell us, experience any unpleasant effects.

THE GREAT EASTERN EXPLOSION.

Readers will have observed that we have not only refused to discuss the so-called science given at the Weymouth inquest, our being that the newspaper reports of that case (which are the only ones accessible to us) did so considerably as to be altogether untrue.

A scientific contemporary, the *Engineer*, less apparently of this consideration, took quite a different course, and published certain severe remarks upon some of the gentlemen who were named. Among others Mr. Galloway, the Chief of Trade Surveyor, was visited with criticism of a somewhat unsparing character. This naturally enough given great offence, and has excited in some professional gentlemen a desire to refute the allegations and refute the arguments of the contemporary. For this purpose they have sent a letter to us, alleging that so much unkindness and hostility to Mr. Galloway is evinced in the article of which they complain that they do not put themselves into communication with the editor who is responsible for it, and request us to publish their rejoinder. Now, to pacify such persons like ourselves, such a proposal cannot possibly be altogether pleasant, because the simple fact of the letter of our correspondents may, though we know, be presumed to constitute an hostility to our contemporary, with whom we have not the slightest desire to wage war. On the other hand, since the reputation of an officer has been attacked by him, and since ourselves believe the attack to have been made unreasonably (although not, we firmly believe, with malicious or vicious intention), we see no sufficient reason why we should refuse to aid in the restoration of the right. But then, again, our correspondents have written a very fierce letter, and we reciprocated the spirit of their antagonism hotly, and we object to everything like a fierceness in what we publish; thus a new duty is created. Well, there is, happily, the old golden rule to guide us even in this case, and by its aid we may perhaps succeed in justice without giving offence. We will, therefore, do by our contemporary as we should wish him to do by us, by publishing our correspondents' statements as free as possible from what is purely sensational or personal. If this course should be of service to either party we shall hold ourselves amply repaid for it, and arm ourselves for the consequences.

THE GREAT EASTERN'S BOILER AND WATER-CASING.

quences. As we dare not, of course, amend, but must simply omit portions of the following letter, we shall not attempt to bring it into a form in which we can wholly approve it. Some things will probably remain which we should prefer to see omitted, but which the necessities of the case require to stand. Intrinsically, however, the communication will be found of a most valuable character. In order to aid the reader in understanding the question, we have had engraved the accompanying illustration, showing the arrangement of all the cocks at the moment of the explosion. With these explanations we produce the letter, which (when pruned) runs as follows:—

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."
October 1st, 1859.

GENTLEMEN,—With the recent catastrophe on board the Great Eastern, the readers of our mechanical and other journals have been regaled these last few weeks almost to surfeiting, and in connection with this sad event has the propensity to mislead been singularly manifest, not only by much of the evidence given at the inquest, but

by many of the various letters, comments, leading articles, and other effusions which have from time to time been introduced to public notice. Nor would we trespass on your valuable space but for a desire to correct several glaring errors to which the pen of a contemporary of yours, whose pages are devoted chiefly to the discussion of mechanical matters, has given publicity.

In an article in the *Engineer*, headed "The Great Eastern," a most unaccountable attack has been made on one of the witnesses who gave evidence at the inquest at Portland, and as the grounds of those charges are as absurd as they are at variance with truth, we beg your patient indulgence while we attempt to set the public right on points on which (thanks to the article we refer to, and others of a kindred character) they are grossly misinformed, and let us state at the outset that we shall speak of what we saw and know from facts, and not from any second-hand reports of the character contributed by "our correspondent, a practical engineer."

The first indication of that disregard for truth which appears to characterise the writer of that

article, is the extraordinary statement set forth in the report of the Portland proceedings that "he" (Mr. Galloway) "reported that the machinery worked well, and saw nothing wrong." To whom, may we ask, was this report made, and when? Was it to the Board of Trade before the ship left Deptford?—which, by the way, would have been somewhat premature—or to the Board of Trade on her arrival at her destination?—which seems scarcely consistent with common sense—or was it telegraphed from the North Foreland light to Whitehall? No member of the Board was within 100 miles of the vessel, and no verbal communication was therefore possible. Allow us, then, to repeat the question, To whom and when was it made?

But the writer grows complimentary, and favours his readers with his solemn conviction that "of all the evidence at once oracular and impracticable which was elicited upon the inquest, that of Mr. Galloway must take the first rank. Mr. Galloway" (he further observes), "does not speak at trifles, but is accustomed to deliver himself with a straightforwardness and energy which always goes far to enforce conviction." Now, this is not very delicate criticism, and exception might fairly be taken to it on several grounds. But there are questions of greater interest than that of this writer's good taste awaiting our consideration—questions of the deepest import to every one, whether concerned or not in this terrible tragedy; let us take them in order, and see how far the *Engineer* is justified in making his assertions.

There are at least six points on which he differs from Mr. Galloway, to say nothing of those on which he differs from every one else:—1st., the quantity of water in the heater at the time of the explosion; 2nd., the temperature in the chimney; 3rd., the use, or otherwise, of the stand-pipe or a safety valve; 4th., the strength of the heater; 5th., the pressure acting on it; and, 6th., the immediate cause of the explosion. Let us look at these singly and briefly.

First, then, as regards the quantity of water in the casing, the *Engineer* observes:—"The heater, however, must have been nearly or quite full of water at the time of the explosion; it must have been left full after the donkey had ceased to pump through it, and the stop-cock being shut there was afterwards no outlet whatever for either steam or water." What a pity it is the *Engineer* did not either go into this matter himself or make more searching inquiries of "our correspondent" before he arrived at this conclusion. Notwithstanding the terrible emphasis he lays on that little word *must*, let us assure him that one of these cocks was open some time after the donkey engine had ceased to act. The *Engineer* is probably not even aware that each boiler was fitted with two stop-cocks. Such, however, is the fact, and if "our correspondent" had made the inquiries which others did he would have learned that although one was securely shut the other had been partly open; and there is reason to believe continued so till within an hour or two of the explosion. With this cock open so long after the feed was shut off, there could have been but a very little water in the casing. But independently of this—which is a most important consideration—the fact that there was only a small quantity of water there is corroborated most satisfactorily by the appearance of the plates after the catastrophe had occurred, many of them exhibiting indubitable proofs of having been red hot. With these facts before us we would recommend to the *Engineer* a re-consideration of that little word "*must*."

In noticing our first point of difference, it will be seen that we have to some extent anticipated the second—the heat of the funnel. We cannot help remarking, however, in passing, that effective indeed must be that boiler that can usefully employ so much of its heat for evaporative purposes as to leave only 325° to escape through the chimney. There are few marine steam-boilers where it would not be found, if a pyrometer were inserted at the base of the chimney, that 1000°

instead of 325° passed away unemployable. The data, therefore, on which the *Engineer* rests his assumption, that the constructors of these boilers never supposed the water in these casings would boil, is somewhat difficult to comprehend.

3rd. The stand-pipe as a substitute for a safety-valve in this case is next denounced in terms neither choice nor measured, and with a confidence and energy delightful to observe. Here is an extract or two:—

"Steam was formed faster we have no doubt than the small cock in the bottom of the stand-pipe could have discharged, had it been open."

"Such of the witnesses as stated under oath that had the stop-cock been open there could have been no explosion, certainly stated much more than they could possibly have known."

"We still believe that the stop-cock, even had it been open, would not have furnished a sufficient outlet for the steam which the heater proved itself capable of generating."

Now, the efficiency of this unfortunate cock may be settled in a few words. If the *Engineer* will take the trouble to read the evidence of Mr. James Patrick, as it is reported in the journal we have referred to, he will find that after the explosion he went immediately to the cock on the after chimney, and finding it closed, opened it; whereupon it discharged the pent-up steam, and acted well during the remainder of the voyage. Now, if this cock was large enough to discharge the accumulated contents of this jacket (for it is reasonable to suppose there was a considerable volume of steam in it), as well as the quantity being generated during the time of the discharge, does it not appear reasonable that it should be sufficiently large to pass off any quantity that could be formed in the ordinary process of evaporation. If large enough to give easily free egress to a body of steam all but capable of rending it, surely it was every way adequate to fulfil its legitimate functions.

4th. The strength of the chimney to resist the external pressure is thus spoken of:—"As a boiler it had one flue 6 ft. in diameter, and 40 ft. long—the iron being half-inch thick—and without stays of any kind." Without stopping to inquire into the desirability of staying circular boilers—a practice by no means common in the neighbourhood of London—allow us to observe that if "our correspondent" had taken the advantage of the detached part of the funnel lying on the deck to examine its interior, he would doubtless have seen, as others saw, that it was stayed about every 4 ft. or 4 ft. 6 ins. from the top upwards with stays not unlike a flattened tripod, three bars radiating at equal distances from one common centre, and securely attached at their extremities to the periphery of the circle. Admitting, therefore, the correctness of Mr. Fairbairn's theory, which allows to the external cylinder a capability of resistance between three and four times greater than the interior one when unstayed, the presence of stays in this instance would tend greatly to equalise the relative strength of the two, if, indeed, the flue or inner cylinder would not by this means be made even stronger than the other. I refer to this chiefly as clearing the way for the next question.

5th. The pressure in the casing. In the report of his examination at the inquiry, Mr. Galloway was made to say that in his opinion "the collapse and consequent explosion resulted from a pressure of at least 500 lbs. per square inch." Now this, as will appear from a letter received from him on the subject, and a copy of which will be found appended to this, is incorrect. "The question was not what was the pressure in the heater at the time of the explosion," but "what was the force that produced the explosion," or words to that effect, to which he readily replied a force of something more than 500 lbs. on the square inch, clearly indicating that he attributed the collapse, the explosion, and the leaping of the funnel into the air, to something more than the mere pressure of the steam. But more of this anon. That the steam confined in this casing had acquired a fearful degree of density is unquestionable; that it

was more than the *Engineer* supposes, or even twice that, is exceedingly probable. The great heat to which that small quantity of water was subjected, and the fact that for an hour or two all escape was prevented, making such a conjecture in the highest degree reasonable.

But we must hasten to the sixth and most important matter to be discussed, to wit, The immediate cause of the explosion.

In coming to this question we have, we shall presume, established satisfactorily, among other things, three very important points, all of which we shall do well to bear in mind while proceeding to the consideration of the most vital question of all. We have seen that a very small quantity of water in the heater at the time of the collapse is more than a mere probability, indeed, it might be almost established as a certainty. We have seen, too, that the plates of the inner tube or chimney were at the same time, on account of the great heat to which they were exposed, in a condition but little able to resist the pressure from without, and the third question, of the amount of that pressure, though it can never be accurately determined, may be safely stated for argument's sake at 75 lbs. per square inch, an ample force to do what it did. Now, put these three together, and ask any man whose intellect is not hopelessly obtuse what the result must be, and ninety-nine out of every hundred would unhesitatingly affirm that the internal flue in its weakest part would collapse; that when the water came in contact with the red-hot plates hydrogen gas would be formed; that if only a small aperture was created by the flattening of the flue this gas would burn with a steady jet of flame, and thus escape harmlessly into the chimney; but, that if it was rent and a rupture of any magnitude formed, the oxygen in a large quantity meeting the other at the mouth of the orifice would explode and produce results strongly resembling those of gunpowder. We take it that any man not absolutely in a straight waistcoat would, if these facts were placed lucidly and succinctly before him, state this as his belief. And is it not reasonable? What more probable than that the red hot flue should yield to the surrounding pressure? A force of considerably less than 75 lbs. per sq. in. would accomplish this. What more natural to suppose than that in bending it should break and open an extensive communication between the chimney and the casing? And what, when this was effected, was to hinder the ordinary chemical combination and its results?

But the combined evidence of Messrs. Faraday, Brande, and Taylor are shaken at the unfortunate Surveyor like a rod at a boy, and his attention directed thereto as a something which, if marked, learned, and inwardly digested, is likely to do him good. Verily we are at a loss to see anything in either of these reports, which are now lying before us, affecting the question. Let one or all of these learned gentlemen assure us, if they can, that oxygen and hydrogen of equal proportions, or nearly so, if brought into contact under these circumstances would not produce an explosion, and explain why, and we will see what light that throws on the matter; but until we are shown that, we must remain sceptical on the *Engineer's* theory that it was only an excess of steam in the casing.

Again, if the *Engineer* will put pencil to paper and ascertain the force required to separate in the direction of its length a cylinder 7 ft. in diameter and $\frac{1}{2}$ in. thick, he will not be long probably (or ought not to be) in discovering that it would require a strain of about 1,890 tons to tear these plates asunder; and when it is remembered that after it was discovered this piece of funnel and casing, weighing of itself between 11 and 12 tons, was shot 30 feet in the air, breaking in its ascent the waste steam and other pipes attached to it as well as the funnel stays which secured it to the ship, will it, we ask, be entertained by any man in his senses that all this was effected by a paltry pressure of 75 lbs. per square inch?

Another and very remarkable appearance presented by the outer casing is strongly suggestive of the fact that some other power than mere high pressure steam produced the havoc of that day.

On examining the detached piece of funnel on deck, the outer cylinder was observed not only to have retained its shape in the most perfect manner, but with the exception of the granular and serrated appearance of the fracture, one would almost have supposed it had been cut off in a lathe, so regular and even was the line at which it parted; and this, too, while the internal flue was crumpled up like a sheet of paper under the pressure of the hand. Does not this convey the idea that some irresistible power acting suddenly and forcibly—some power of which, probably, we know but little—was at work, and not only disconnected the upper part of the funnel, but lifted it on deck afterwards? A little below this line a piece of plate a foot and a-half or more in area, was forced clean out of the solid metal, and that, too, without affecting the parts contiguous to it, just as we sometimes see a hole made through a pane of glass by a quick sharp blow, without leaving the trace of a star.

We might multiply proof upon proof, but enough has been said to place beyond all doubt the fact that something greater than the force of steam, even of twice or thrice 75 lbs., did the execution of that terrible evening. What a thousand pities that the writer of that article did not think twice, or at all events inquire twice, before he wrote once. But, we presume, it is "our correspondent" the "practical engineer" who is to blame—perhaps so.

The very flattering allusion made in the article we allude to by its highly-gifted author to Mr. Galloway, the latter gentleman must fully appreciate; if not, he deserves to suffer the consequences. It runs to the following effect:—

"From the evidence of such men" (Professors Faraday, Brande, and Taylor) "the public will perceive how to estimate that of Mr. Galloway, which is, if possible, more ridiculous than the notable report which a few individuals busied themselves in getting up soon after the explosion," &c., &c. Now, we can see no difficulty in reconciling the statements in both Mr. Galloway's evidence and the report of these great chemists. To our mind they agree marvellously.

Thus much, Gentlemen, on this matter. Let us in conclusion observe, first, that the statement in the paper just quoted, that "in regard to the actual connection of the pipes, no explanation appears to have been given at the inquest," &c., is entirely without foundation—we might almost use a stronger term. The fact is, Mr. Galloway drew out an elaborate plan, showing the arrangement of the pipes, cocks, donkeys, &c., and explained the details of the accident by its aid, it being spread at the time on the table at which the jury were sitting. We might further also observe that at the conclusion of his evidence the jury expressed their acknowledgements to Mr. Galloway for the information they had derived from it. Where was "our correspondent," not to have seen all this?

But even the verdict does not please this amiable man; he grumbles because the jury found, what he affirms "no human tribunal" was competent to find, or, in other words, what he would not have found, viz., "that the bursting was caused by the closing of the tap," &c. Why, what on earth would he have had the jury do? Did not every fact that was elicited point to that as the direct and immediate cause of the calamity? Was it not clear enough for every simpleton to understand? And yet it almost seems not. There are some people who shut their eyes at noon-day, and call it night—who argue in foregone conclusions, and make the result of their deliberations accord with their preconceived notions; twelve such men would be a treasure of a jury. With a very slight stretch of the imagination we can conceive their verdict in this case; it would in all probability be something to the following effect:—*Died by the visitation of some demon of mischief, though what he did, or how he did it, there is no evidence to show.*

We are, Gentlemen, most obediently yours,
COMMON SENSE.

[Corr.]

6 Adelaide-place, London Bridge,
Sept. 26, 1859.

MY DEAR SIR,—Thanks for drawing my attention to the article in the *Engineer*; it is quite clear I have been misunderstood about the pressure. I am sure no person will believe that I considered more than 400 or 500 lbs per square inch would be necessary to collapse the inner casing (which I believe to have been red hot); what I meant to convey (and trust I did to some people) was, that it would require more than 400 or 500 lbs. to separate the outer casing.

The question was put to me after I had stated the inner casing collapsed, &c., and I naturally inferred it applied to the bursting of the outer cylinder.

The article in the *Engineer* I consider of too personal a character to reply to, but please set the matter of pressure right with your friends.

I am sure you will consider my experience with boilers sufficient to know that it does not take very great pressure to force down the crown of a furnace when red-hot.

I am, my dear Sir, yours very truly,

R. GALLOWAY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I am not about to discuss the question who was in charge of the engines and boilers, or who was the cause of the explosion, having only a right to interfere on public grounds, and to further the research as to the real cause with a view to a prevention of such calamities.

I have for a considerable time called the attention of the public to the frequency of boiler explosions, and their probable increase unless more attention be paid to the construction and management, and more particularly to that form of boiler known as the Cornish boiler, in which the pressure is exerted upon the outer portion of a cylinder. In April, 1855, I wrote a letter to the *Manchester Guardian* paper on this particular form of boiler, which begun thus:—

"Another boiler explosion, attended with a lamentable loss of life, is recorded in your journal of this day. Pending the judicial inquiry which must take place into the facts of that case, I do not intend to comment on the details as set forth in your report, beyond calling attention to the fact, that the part of the boiler which has given way and occasioned this lamentable catastrophe, is one of its internal flues, which had to sustain a great pressure exerted externally upon its cylinder-like form, and which at length failed under the strain to which it was subjected. The many instances of boiler explosions arising from the collapse of internal flues of this character, ought surely to induce a more serious inquiry than the subject has yet received, with the view of ascertaining whether boilers of this, the favourite form of construction, are safe, when worked at the high pressure now deemed desirable, or, indeed, at any considerable pressure; or whether a collapse of the flues is not a certain result of the force so applied, and in the best of boilers, and under the most favourable conditions, only a question of time. For myself, from inquiry and reasoning upon the subject, I have long since arrived at the conclusion that this form of boiler, whether of the kind known as the Butterley or the Cornish, is not safe;" and at Leeds, last year, I read a paper on the subject before section G of the British Association, which you were kind enough to publish in the *MECHANICS' MAGAZINE* of Oct. 23rd, 1858. The portion of the boiler that exploded on the Great Eastern was the portion of the flue or chimney extending from the top of the boiler to the upper deck; that flue or chimney was surrounded by another cylinder 12 inches larger than the internal flue, being seven feet diameter, leaving a water space of six inches betwixt the flue and the case, and extending in height, or length, forty feet from the boiler, which, when charged with water, would exert a pressure of 18 lbs. per square inch at the bottom, internal to the outer shell or case, and external to the flue or chimney.

The outer shell, or case, was provided with an open stand-pipe from the bottom, and extending to a height of twenty-five feet above the top of the case, and in the form of an inverted syphon, the descending pipe being attached to the top of the outer shell. At the extreme height, and in the curve of the syphon, a half-inch hole was bored, and at all times open to the atmosphere; on the descending leg of the pipe just at the top of the water-space was inserted a stop-tap, to cut off the communication of the steam from entering the descending pipe, or short leg of the syphon.

Having now described this portion of the boiler to the best of my information, I will now endeavour to explain the cause of the collapse of the flue. It was stated in evidence that the supply of water to the outer case was stopped, and that the tap on the short leg of the stand-pipe was closed; such being the case, I shall endeavour to show that the construction of water heater of this peculiar description is one highly dangerous, not on account of the heat which traverses its surface, but from the fact of a 6-foot tube being exposed to the pressure which would be exerted external to its diameter.

Many parties imagine that the heat given from the furnaces when passing up the chimney would be at a very high temperature, and consequently there would be a rapid generation of steam in the case; and by the tap being closed there would be an immense pressure brought to bear upon that chimney, or flue, or water-heater. In the first place I assert the heat thus traversing through the flue would never exceed 450 degrees Fahrenheit, and I very much question whether it would reach 350 degrees in so large a space as a 6-foot diameter flue. In making this statement I do not merely imagine such would be the heat given out; my conclusions are from the actual test of a similar boiler; but I will grant that the temperature was 450 degrees in the flue, at which temperature it would at the very least take twelve hours to get the water in the case to boiling point, and to generate a pressure of steam of 20 lbs. above atmosphere would be 260 degrees in the case, which I aver was never the case in the exploded funnel.

It now remains to prove the real pressure of steam that would have to be generated in the heater sufficient to force the water out at the top of the pipe. It must be borne in mind that the 14-inch stand-pipe was inserted in at the bottom end of the case, and was open from end to end, extending to a height of twenty-five feet above the top of the case, and that there was a 1-inch hole at the top to let out the steam from the heater, or, as in the case at the time of the explosion, to let out the water when the tap on the top of the water heater was closed. There requires no comment as to the probable pressure of steam in the case; a pressure of 11 lbs. per square inch was sufficient to force the water out at the top of the pipe, and thus I come to the undeniable conclusion that the steam in the case did not exceed 11 lbs. per square inch at any time; had the tap been open the half-inch hole would have been sufficient to have discharged as much steam as twenty such water heaters would have generated.

Having now proved that the steam pressure could not be more than 11 lbs., I come to another feature regarding the pressure brought to bear externally upon the 6-foot diameter. The water-heater, as described, was forty feet high, and unless it was completely filled with water, none could be supplied to the boiler; thus a column of water of that height would exert a pressure of nearly 18 lbs. per square inch at the bottom end of the case, and that added to the pressure in the stand-pipe gives a total of 29 lbs. per square inch, as being the extreme pressure that could be brought upon the water heater; now the question arises at what pressure did that internal flue collapse; it is perfectly clear that it collapsed at less than 29 lbs. per square inch; therefore, the flue must have been weaker than the stand-pipe denotes, being constructed, as they perhaps presumed, to work with safety at 29 lbs. per square inch.

Now I have repeatedly called the attention of boiler owners to the case of the Victoria, whose boilers twice collapsed and killed eleven persons. A searching inquiry took place as to the cause.

The Victoria exploded in 1838; the flues were six feet diameter, made of $\frac{1}{4}$ -inch Low Moor plates, and collapsed at a pressure of 18 lbs. per square inch, viz., 10 lbs. of steam, and 8 lbs. of a column of water. She was repaired, and again collapsed at the same pressure. The collapse on board the Great Eastern is precisely similar, except that the flue is six feet diameter, with $\frac{1}{4}$ -inch plates, yet we find that although double the thickness of the Victoria, there is no proof that it took more or less than double the pressure, 26 lbs., to collapse the flue on the Great Eastern, as there was no means of ascertaining what was the height of the column of water in the stand-pipe; but certain it is that it collapsed under 26 lbs. pressure. I am fully persuaded that the cause of the collapse of the flue on the Great Eastern was from defective construction, and that the pressure exerted external to the six-foot flue was too much for that diameter to resist.

As a water heater I should denounce it as being highly dangerous, arranged as it is, in having a stand-pipe attached so as to increase the pressure to such an extent. There is no doubt that the impression was that the flue was sufficiently strong to carry that pressure, otherwise the stand-pipe would not have been erected, and therefore the blame is not justly on the person who closed the tap; although I acknowledge the explosion would not then have occurred had the tap been open; but it remains with those who applied the stand-pipe, whether they considered the flue sufficiently strong to resist the pressure the stand-pipe would bring upon it in case of the tap being closed. I cannot but think that such was the opinion, or why have carried that stand-pipe to such an elevation? Many instances of collapse similar to the one already mentioned could be adduced.

Having occupied so much of your space, I will not detail them, but I trust a reminder of the dreadful occurrence will cause a thorough inquiry whether the economy attendant upon the use of those large and dangerous vessels for heating water in connection with the boilers is really so efficacious as imagined, or whether they might not be made more useful for heating water for ships' purposes.

Your obedient servant,

J. HOPKINSON.

Britannia Works, Huddersfield, Oct. 4th, 1859.

AERIAL NAVIGATION.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—This subject having been revived since I wrote to you thereon (see MECHANICS' MAGAZINE, vol. 50, p. 439), I beg space for a few remarks.

Balloons have long fulfilled two of the requirements for navigating the air; viz., ascent and descent at the will of the aeronaut. Two more requirements, however, exist, the ability to travel in any required direction and against any wind, and steerage. These desiderata present formidable mechanical difficulties, but not, I think, insurmountable ones. Steam-power and a proper form must be adopted. The air in a hurricane is stated to travel at the rate of 80 miles an hour, and to exert a pressure of nearly 32 lbs. per square foot. The aerial vessels should, therefore, be able to travel at the rate of 100 miles an hour, at which rate the pressure of the air would probably be nearly 50 lbs. per square foot of flat surface. To reduce the resistance I should propose a vessel of the form shown in the diagrams: Fig. 1, a side view, and Fig. 2, an end view from the head. Great size is indispensable: say 800 feet long by 100 diameter. This would displace about 150 tons of atmospheric air, and probably a light high-pressure boiler and engine, with surface condenser, working up to 1,000-horse power, would propel it in the teeth of a hurricane; but as violent winds are seldom met with at any great height, a much smaller power would generally

suffice. However, as at the end of a voyage a gale may be blowing, the power should be at hand.

In the diagrams *a* is the body of the vessel. This may be made of light woodwork, or very thin steel or copper, on the cellular plan for insuring stiffness with little weight. Timbers of wood perforated with centre-bits would be light and strong. Partitions should be made with cross and longitudinal bulkheads, a centre division being the engine-room, &c. Each compartment (except the engine-room) should have an air-tight bag made to fit it internally, but not fixed in any part, so that it may be wholly or partially filled with hydrogen gas, but never quite filled. The weight of the gas would be about 10 tons—engine, say 50 tons; leaving 90 tons for the hull, propellers, crew, provisions, fuel, &c. *b* is one of the propellers. These may be formed of canvas or india-rubber cloth, with tubular ribs or extending arms. By connecting each arm with a separate crank, say 36 arms and the same number of cranks, each one set 10 degs. away from the next, a perfect wave motion of

the wings will be obtained, far preferable to any screw propeller.* *c* is the tail or rudder, which would move in a similar manner to the tail of a fish (the mechanism would take too much of your space to describe, it is, however, light, and not easily put out of order), and moves in a curve, unlike a rudder. *d* is a spar for supporting the ballast *e*, a flat piece of iron, to keep the hull upright, and by the ropes *f* to assist in ascending and descending, by pulling upon the aft or forward ropes, and causing the head to incline upwards or downwards.

If such a vessel as the above can be constructed the mails may be carried to Australia in six days. Captain Norton could also make use of it in war, the balls and shells being merely dropped upon the enemy; guns of any kind not being requisite.

I have not made any experiments upon the resistance of different forms moving in air. A hundred miles an hour would be 1,600 feet per minute; the area of midship section would be 7,854 feet, and by finding the resistance per square foot of section of a given form, the required horse power may be calculated.

Writers on this subject speak of birds as inflating their quills, &c., with air for the purpose of altering their specific gravity. I think they perform the latter by producing a vacuum. And if the above vessel can be made to bear fifteen pounds per square inch external pressure, a vacuum might be formed by the engine, and ten tons weight of gas, and about the same weight of air-tight bags, would be saved.

I am, Gentlemen, your obedient servant,

T. MOY.

Clifford's Inn, Oct. 4, 1859.

THE GREAT EASTERN TRIAL TRIP.

PADDLE ENGINES.

We have been furnished, at the last moment before going to press, with the following statement, which we believe to be reliable:—

Started from Portland October 8th, at 2.45 p.m. Draught of Water, 20 feet 6 inches fore, 25 feet aft.

LIGHTS.	Time of passing.	—	Distance in knots.	Length of time.	Speed per hour.	Average Revols. per Min.	Time.	No. of Revols.	Average per Min.
Bill of Portland	5.40 p.m.	Bill of Portland to Eddystone. }	73	5.30	13.27	9.41	5 to 8 p.m.	1755	9.75

Total distance run from Bill of Portland Light to Tuscar Light, 400 Knots

Giving a slip of " by Paddle Wheels 456 "

Diameter of Wheel, 56 feet outside Floats.

Floats reefed, ... 2 feet 8 inches.

Giving diameter of Wheel, 51 " 0 " outside Floats.

Effective diameter on trial, 48 " 0 " (From centre to centre of Floats).

Number of immersed Floats on each Wheel, 6.

Slue of Floats, 3 feet by 13 inches.

Total area of immersed Floats, 468 square feet.

Total area of immersed Midship section, 1588.38 square feet.

Total Steam Pressures:—(Vacuum 27 lbs.)

From starting at 5.0 p.m. to 8.0 a.m. October 9th 17 lbs. in Boilers.

" " 8.0 a.m. " 8.0 p.m. 25 " "

" " 8.0 p.m. " 8.0 a.m. October 10th 17 " "

" " 8.0 a.m. till Engines stopped 22 to 25 " "

Consumption of Coal, at the rate of 95 tons 6 cwt. 28 lbs. in 24 hours.

* A similar propeller may be constructed for steam-vessels.

NEW PROPELLERS AND THEIR CONSTRUCTION.

EDITORS OF THE "MECHANICS' MAGAZINE."
GENTLEMEN,—The study of this valuable and
at marine agent having engaged my
n for upwards of seven years will, I trust,
efficient apology, not only for my offering
uggestions on the same, but also claiming a
your valuable journal for their insertion,
ly as the subject is taxing at the present
to the utmost extent, the minds and in-
of the scientific world. Numerous reports
trips, and letters from various individuals,
g and also advocating certain curves and
n the formation and construction of the
r fans have from time to time occupied
f your space, still we find little or no pro-
s (see *United Service Gazette*, 3rd ult.),
s regards augmentation of speed or reduc-
its vibration, evidently proving that an
is error in its construction still exists.
ppellation of *Sorew* being associated with
marine propeller has been fatal to its
or improvement, inasmuch as the idea
, and, strange to say, still cherished, is
must necessarily partake or assume a *sorew*-
struction by imparting certain curves or
o the blades; numerous claims (as before
o) have been made to these strange dogmas
liances, each contending for that which is
y perfectly useless, but in fact injurious,
rmation of which allow me to ask, Do we
curve or twist imparted to the vanes of a
ll? or the smoke jack? or the simple toy
ve sometimes see children bounding along
ets with? Certainly not; on reflection it
obvious that its presence in either case
e a serious drawback, it might, therefore,
nably inferred that wherever it exists in
w propeller, an excruciating or floundery
lency must be and is produced, instead of
er, on the contrary, being extruded off
with the boss, leaving little or no trace of
eller. Other injurious results consequent
rence are produced, viz., vibration—also
sary absorption of steam-power, arising
inability to work freely, resulting also
f speed.
tion is also produced from other causes,
screw working into instead of independent
stern-post; two-bladed screws tend con-
y to increase the same, arising from their
of uniformity of power, one blade fre-
being only partially immersed, and at the
ne seriously affecting and inflicting con-
wear and tear to the engines, disadvan-
id drawbacks which cannot be got rid of
a lifting screw.
ig adverted to some of the causes and
ks under which this submarine propeller
ring, the question asked will be, Are they
ntable? Unquestionably they are.
e construction of what is designated the
propeller, preference should be given to
rather than to long narrow blades, avoid-
les and curves (as before noticed), especially
g against the greater amount of surface
ng the boss (as some screws are constructed),
a sad mistake, from the circumstance of its
proximity to the centre, being the most
and inactive part: here the water should
tolerable free passage, and must produce
of no ordinary character. Again, no real or
tory results can be expected or achieved
e pitch is at all times alterable in order to
very contingency, the absence of which has
g felt in the steam screw marine, an object
lesirable and paramount towards its de-
st and solution, it being a well-known
at two vessels constructed in every respect
ngines and screws the same, still the speed
shall be greater than the other—a powerful
nt, indicative of the utility and advantages
assessed by the feathering screw.
clusion, I would briefly recommend and
locate the adoption of the feathering
or the reasons before assigned; secondly,

flat circular blades (see *MECHANICS' MAGAZINE*,
No. 24, June 10th, page 381); and lastly, four
blades, the combination of which would be found
to entirely dispense with all the aforesaid draw-
backs, and secure a greater speed than has ever yet
been attained. Respectfully apologising for having
occupied so much of your valuable space,
I have the honour to be, Gentlemen,
Your most obedient servant,
WILLIAM HEWITT.

Bristol, October.

NOTICES.

The *MECHANICS' MAGAZINE* will be sent free by post to
all subscribers of £1 1s. 8d., annually, *payable in advance*.
Post Office Orders to be made payable to R. A. Brooman, at
the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column
are charged at the rate of 5d. per line for any number of
insertions less than 13; for 13 insertions, 4d. per line; and
for 52 insertions, 3d. per line.
Each line consists of 10 words, the first line counting as
two. Wood-cuts are charged at the same rate as type for
the space occupied.
Special Arrangements for larger or Serial Advertisements
To ensure insertion, Advertisements must reach the Office
by 5 o'clock on Thursday evening each week. None can
be received after that time for the ensuing number.

Our Weekly Gossip.

A correspondent writes:—"In the *Times* of this
day (Wednesday), the special correspondent writing
from Holyhead, tells us that the little rolling which
took place during the passage round, was owing to
the centre of gravity being below the centre of motion.
I should be glad to learn how it is that the Great
Eastern has a centre which no other ship was ever
known to possess, inasmuch as the centre of gravity
is as much a centre of motion as any other point in
the ship, there being (in the act of rolling), motion
about every point in the ship as a moveable centre,
and about no point as a fixed centre."

The troop ship *John Duncan*, now lying in the
London Docks, affords another remarkable instance of
the advantages of having an *efficient means of lower-*
ing the boats on ship-board, and we may well infer,
if the use of such a means for saving life has been
turned to such good account (three lives having been
saved on different occasions in the single voyage of
one ship), what general public advantage must ensue
if such were carried in all ships. We again proclaim
the painful fact, that ships in the Royal Navy and
government, emigrant, and troop and convict ships,
are almost the only ships in which anything of the
kind is ever taken. The log of the *John Duncan*, in
which ship Clifford's lowering apparatus was fitted in
accordance with the Government charter party, by
order of the Admiralty, states, "That in latitude 32°
south, and longitude 78° 30' east, when the ship was
going 8½ knots per hour with a heavy cross sea, the
starboard life boat was lowered by it, with an officer
and six men, to pick up one of the soldiers who had
fallen overboard from the fore-castle deck; that the
man was picked up, and in fifteen minutes the boat
was again at the davits, and the man in his cot." Again,
"while on the passage from Calcutta to Trinidad, with coolies, when in latitude 1° 17' north,
longitude 89° 22' east, at 4:30 a.m., one of the coolies
fell overboard, but the same boat was again lowered,
and the man picked up in ten minutes, although the
ship was going nine knots the hour at the time." The
last occasion was "when in latitude 21° 14' south,
and longitude 8° 27' east, while the ship was going
6½ knots, another of the coolies fell overboard, and in
six minutes after he was picked up through the same
means."

The following letter on a similar subject deserves a
place:—

11 Victoria Terrace, Notting Hill, W.,
12th October, 1859.

GENTLEMEN,—As you mention with reference to
the recent meeting of the British Association at
Aberdeen, that my paper on my recently patented
invention for disengaging ship's boats at sea was not
read, I beg to inform you that the omission was
solely in consequence of my urgent and sudden recall
to duty earlier than I had anticipated before setting
out for Scotland. I wished very much to have availed
myself of the opportunity thus afforded me of making
it publicly known, and especially to the naval
authorities, whose attention I wished more particularly
to engage, as my method would tend considerably to
facilitate the manoeuvres of H.M. ships of all classes,
and particularly of gun-boats, and such as work in

shallow water when disembarking men and landing
assault parties under fire of batteries (especially if
the latter be fitted with the revolving stage or slide,
as noticed in your paper), after the manner of those
at Cherbourg. My plan does not require the vessel
to stop, but keeping at high speed renders it exceed-
ingly difficult for her assailers to keep up their attack
at once upon herself and boats by reason of the facility
with which the latter would be disengaged unknown
to the enemy. Thanking you for your kind notices,
and trusting to be able at some future time more
fully to demonstrate the utility of my invention,
Believe me, Gentlemen, yours faithfully,
E. A. Wood.

The following letter on the Government specifica-
tion for the Gibraltar cable may be read with advan-
tage:—

30 Adde-street, Wood-street, London,
October 3, 1859.

GENTLEMEN,—I was much pleased from your last
week's Magazine to find that the Government of this
country were going to have a submarine cable laid be-
tween Falmouth and Gibraltar, but I was surprised to
hear that a contract had been entered into with the
Gutta Percha Company for making the core, as I find
there is a specification put out by the Government for
the purpose of giving a contract for the external cover-
ing, completion, and the very hazardous undertaking
of laying the cable. We are, therefore, to have this
great undertaking carried out in the above form, and
I cannot but notice the undue and unfair share of re-
sponsibility which is to devolve on the two con-
tractors. In the first place, the interests of the Gutta
Percha Company appear to be well considered. They
make the core and test it on their own premises, and,
if perfect, receive their money, and thus ends their
responsibility. The contractor for the remaining por-
tion is to bear all other risks, such as removal, varia-
tions in temperature of the atmosphere during
process of covering, and finally, the laying down; and
then subject to forfeit the sum of £20,000 if the
insulation is not kept perfect for thirty days. Now,
Gentlemen, should the continuity be affected when
the cable is at the bottom of the sea, I am at a loss
to understand who can determine whether the fault
will be in the core, or in the external covering not
being properly applied. I am sure you will excuse me
troubling you with these remarks, but in a matter
of such great national importance I think you will
agree with me it is desirable to obtain every informa-
tion, especially as I feel certain the manufacture of
submarine telegraph cables must be very imperfectly
understood, as none of the lines hitherto laid, of any
magnitude, have lasted perfect for any length of time.
I fear I have trespassed too far on your space, but
should you consider these remarks worthy of a space
in your valuable publication, you will oblige your
obedient servant,
A SUBSCRIBER.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

The abridged Specifications of Patents given below are
classified, according to the subjects to which the respective
inventions refer, in the following table. By the system of
classification adopted, the numerical and chronological
order of the specifications is preserved, and combined with
all the advantages of a division into classes. It should be
understood that these abridgements are prepared exclu-
sively for this Magazine from official copies supplied by the
Government, and are therefore the property of the proprie-
tors of this Magazine. Other papers are hereby warned not
to produce them without acknowledgement:—

STEAM ENGINES, &c., 644, 651.
BOILERS AND THEIR FURNACES, &c. *None*.
ROADS AND VEHICLES, including railway plant and car-
riages, saddlery and harness, &c., 640, 653, 665.
SHIPS AND BOATS, including their fittings, 659, 671.
CULTIVATION OF THE SOIL, including agricultural and hor-
se-cultural implements and machines, 648.
FOOD AND BEVERAGES, including apparatus for preparing
food for men and animals, 663.
FIBROUS FABRICS, including machinery for treating fibres,
pulp, paper, &c., 641, 643, 650, 957, 658, 668.
BUILDINGS AND BUILDING MATERIALS, including sewers,
drain-pipes, brick and tile machines, &c., 636, 642.
LIGHTING, HEATING, AND VENTILATING, 637, 633, 672.
FURNITURE AND APPAREL, including household utensils,
time-keepers, jewellery, musical instruments, &c., 633,
640, 647, 654, 667.
METALS, including apparatus for their manufacture,
646.
CHEMISTRY AND PHOTOGRAPHY *None*.
ELECTRICAL APPARATUS, 639, 653.
WARFARE, 662.
LETTER PRESS PRINTING &c. *None*.
MISCELLANEOUS, 634, 635, 638, 642, 644, 652, 655, 656, 660,
661, 664, 666, 669, 670, 674, 675.

633. W. E. NEWTON. "Improvements in the manufacture of shoes and other coverings for the feet." (A communication.) Dated March 13, 1859.

This consists in the manufacture of shoes with their uppers of woollen or other cloth, or felt, and with a sole foxing and binding of india-rubber. *Patent abandoned.*

634. J. PALMER. "A new or improved trap for catching animals, birds, and fishes." Dated March 13, 1859.

This trap consists of a bar of iron to which two hooks are connected. One of the hooks is capable of sliding for a short distance along the said bar, and by its sliding motion to move a small lever at the end of the bar opposite to that at which the hook is situated. The hook described is provided with the bait. The other hook turns upon the joint upon the bar and when thrown back is held by the lever actuated by the bait-hook. A strong coiled spring throws the jointed hook forward with great force when it is disengaged from the said lever. *Patent abandoned.*

635. J. T. CALLOW. "A compound action in cage machinery, with the apparatus connected therewith, having a perforated shield for saving life and property in the event of a rope, band, or chain breaking, or the engine-man drawing the cage too high at coal or other shafts, where slides are applicable, which said invention is also applicable to hoisting or other lifting machines." Dated March 13, 1859.

This consists in the use of two chairs, or a double chair and a perforated shield, which by means of certain levers, joint-rods, and springs prevent the fall of the chair in the event of the rope or chain breaking. There are various details included. *Patent completed.*

636. J. THORNTON. "Improvements in machinery for the manufacture of bricks, tiles, and other similar articles." Dated March 13, 1859.

The principal feature here is in the manner of forming the mould or die, which expands at the time for introducing the rough clay, the sides remaining upright, and the corners or angles remaining closed. The mould is formed of two vertical sides; two of these sides act as jaws to hold the others. These jaws traverse backwards and forwards, carrying with them the other two sides, and on compressing the clay slide between two metal plates which form the top and bottom sides of the bricks. *Patent completed.*

637. J. COURT. "An improvement in nibs for gas-burners." Dated March 13, 1859.

This invention was described and illustrated at page 185, No. 38, Vol. 2, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

638. R. ALLISON. "Improvements in apparatuses for boring and sinking." Dated March 13, 1859.

This invention was described and illustrated at page 199, No. 39, Vol. 2, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

639. J. MACNAB. "Improvements in telegraphing or signalling apparatus." Dated March 13, 1859.

This relates to the working of telegraphic apparatus of various kinds by a line or lines of atmospheric or hydrostatic tubes, such line of tubing being the actual means of communication between the distant points to and from which telegraphic signals are to be sent and received. The end of the tube is fitted with a cylinder and piston, by the agency of which the requisite forcing pressure can be communicated to the fluid contents of the line of pipes, whilst at the receiving stations there is a recording, and, if necessary, a printing, apparatus through which the action of the fluid movement or pressure is communicated in the form of signals. *Patent completed.*

640. B. WALLER. "Improvements in joining leather, flexible and textile materials, for the production of boots and shoes, and articles of the like description, and harness, strapping, bags, sails, tent-covers, portmanteaus, and such other articles, together with machinery and apparatus for that purpose." Dated March 14, 1859.

The patentee claims, 1, the use of sets of continuous wires or metal threads of round, square, corrugated, serrated, screwed, or milled or other shape for being cut and used as pegs in the manufacture of boots, shoes, and textile or flexible materials. 2. A method of drawing and cutting the wires for fastenings, and the manner of supplying and securing the same in the articles or materials. 3. A method of lapping or lasting the uppers of boots and shoes. 4. The use of a rivet plate for boots and shoes. 5. A method of damping and heating, pressing and moulding, the soles of boots and shoes. 6. A method of cutting, burnishing, and finishing the soles and heels, and method of fixing the same. 7. The general arrangement of machinery. *Patent completed.*

641. R. A. BROOMAN. "An improved method of

treating wool and other fibres in order to form threads." (A communication.) Dated March 14, 1859.

This consists in converting alivers or rovings as they come from a carding engine by felting and friction into threads suitable for weaving, without the intervention of any spinning machine. This is effected by an apparatus composed of a series of upper and lower cylinders which turn by frictional contact one with the other, and have at the same time a to and fro horizontal motion. *Patent completed.*

642. A. TYLOR. "Improvements in apparatus for regulating the supply of water to water-closets and other vessels." Dated March 14, 1859.

Here the supply pipe is connected to one end of the top of a chamber, in the bottom of which chamber there is a cylinder in which a piston works. To the other end of the top of the chamber a pipe is connected, and it passes to the pan of the closet. The end of the supply pipe is closed by a valve which is attached to the end of one arm of a lever; the other arm of this lever is by preference of a curved form, and passes through a slot in the piston-rod of the piston which works in the cylinder below. Through the piston there are a number of holes, and to the centre of the bottom of the piston a disc of india is attached, which, when the piston is moved downwards, prevents the passage of water through the holes, but when the piston is moved upwards permits the water to flow through freely. From the bottom of the cylinder a small pipe passes into the chamber above, and on this pipe there is a cock to regulate the speed at which water may flow through the pipes. The piston-rod of the piston passes through a stuffing-box in the top of the chamber, and is attached to the weighted lever to which the handle is ordinarily attached. By these means when the handle is lifted the piston will be moved towards the top of the cylinder, and the valve will be moved away from the end of the supply pipe. The water will then flow through the chamber into the pan until the piston is again forced down. *Patent completed.*

643. T. LIGHTFOOT. "Improvements in fixing colours on woven fabrics or fibrous materials." Dated March 14, 1859.

This consists in exposing to the action of steam cotton fabrics which have been mordanted with salts of alumina or other earthy or metallic salts, or mixtures of salts of alumina or other salts, and subsequently dyed with madder or a preparation of madder or other colouring matters, with a view to cleaning afterwards with soap liquor, commonly called soaping. *Patent completed.*

644. D. JOY. "Improvements in hydraulic engines and meters." Dated March 14, 1859.

This applies, 1, equally to motive power engines and meters, and consists in making the working cylinder of the machine reciprocate within a chest, while the valve for induction and eduction remains stationary. The cylinder is moved at each end of the stroke either by mechanical means like a valve, or, in revolving engines, by the piston itself coming in contact with the end of the cylinder, or by other means. It applies, 2, to the ordinary form of hydraulic hoist and water engine, and consists in the use of two or more cylinders and rams working within each other telescopically, which forms a hoist of various powers, the water being admitted to any of the cylinders according to the weight to be lifted. Also in these and the ordinary form of engine when the patentee uses a slide valve, he places on the back of that valve one or more small slack valves over that part which closes the port at top as relief valves to the port when thus covered. *Patent completed.*

645. C. H. HURST. "An improved wrench or spanner." Dated March 14, 1859.

This consists in so constructing a wrench or spanner that when in use it shall not damage the article to which it is applied, and for certain articles—such as taps or cocks—it shall be self-adjusting. It also consists in making the jaws of the wrench or spanner somewhat similar in form to the article to which they are to be applied. *Patent completed.*

646. E. SMITH. "Improvements in treating or preparing furnaces used in the manufacture of iron." Dated March 14, 1859.

This relates to mill furnaces and puddling furnaces. The inventor lines the interior of mill furnaces with calcined pebbles or flints, reduced to a powder and made into a paste with water. The slag obtained from mill furnaces formed in this way is used for lining puddling furnaces. *Patent abandoned.*

647. T. PATSTONE. "Improvements in shades or glasses for gas and other lamps, and in the supports of the said shades or glasses." Dated March 14, 1859.

The patentee claims, 1, covering the upper part of the shade or glass with a dome or other shaped cover, carried by and supported upon a lining or support perforated with holes, the said lining or support carry-

ing the cover resting either on the edge of the shade or glass, or being supported upon the top of a rod from the gas pipe or lamp stand. 2. Making the said supports or holders of glass by which the shadow of the ordinary holder is avoided, and an ornamental appearance given to the shade or glass. *Patent completed.*

648. J. S. DAWES. "A new or improved method, or combination of arrangements for the better securing and collecting of night-soil or town manure, and rendering it more valuable for agricultural purposes." Dated March 14, 1859.

This consists in so constructing closets, &c., that the excreta may be collected in movable receptacles without nuisance or any admixture of water or rubbish, and sufficiently deodorising the same by mixing with it the fine ashes and cinders produced in the house fires, or by other disinfecting agents. *Patent completed.*

649. W. LANGTON. "Improvements in the manufacture of keys and wood-fastenings used in constructing railways." Dated March 15, 1859.

Here the keys and wood fastenings are compressed and charred, and it is preferred that the keys and wood fastenings when having parallel sides should be forced through a highly heated die, formed internally to the section of the desired fastening; pieces of wood of larger dimensions than the die are in succession forced through the highly-heated die, by which they will become compressed and charred. When wood fastenings are desired to be larger at one end than the other, it is preferred to force the pieces of wood into a properly shaped and highly-heated die, and then to force the charred fastenings back out of the die, or the dies used may be, in parts, made capable of movement; or the die is used and the means of compressing and charring may be otherwise varied. *Patent completed.*

650. C. DESURMONT and C. GOUDRAU. "Certain improvements in looms for weaving." Dated March 15, 1859.

This relates to apparatus to be applied to looms for weaving figured fabrics, and has for its object the obtaining of greater speed in the action of the lames or heddles by means of a double action. It consists, 1, in the use of two presses or slides in combination with hooks and levers for raising the lames or heddles alternately. 2. In a peculiar arrangement of levers for lowering the heddles or lames. 3. In the construction and combination of a design composer, or endless tappet or rack which permits a design to be immediately formed or changed. *Patent completed.*

651. G. B. GALLOWAY. "Improvements upon and in connection with, his former patents, and in the manufacture of fuel, and working steam-engines more economically." Dated March 15, 1859.

This invention is not described apart from the drawings. *Patent completed.*

652. C. RITCHIE. "Improvements in calculating machines." Dated March 15, 1859.

This consists of a box or casing with a faceplate like a dial, upon which are circles graduated for different quantities of time, money, goods, &c. Over this faceplate are two or more bands, which being suitably actuated internally point to the given and required quantities or numbers. *Patent abandoned.*

653. W. CLARK. "Improvements in the apparatus of electric lamps or lights." (A communication.) Dated March 15, 1859.

This invention is not intelligibly described apart from the drawings. *Patent completed.*

654. B. RIDER. "Improvements in hats, caps, and other coverings for the head, and in the apparatus used in the manufacture of such articles." Dated March 15, 1859.

This consists in preparing hat bodies of two thicknesses of sheet cork with a fabric of net, &c. between the two. In forming helmets of two thicknesses of felt cork-shavings or wool dust being placed between the two thicknesses of felt. In making cap peaks of several thicknesses of fabrics caused to adhere together by cement, consolidating them by hot pressure. In ironing up hat bodies with a mixture of gum damar and French chalk. In using in the manufacture of hat bodies an adhesive matter formed of saccharine matter and shellac. It also consists in coating the leather linings of hats with silk, cotton, willow, ground cork, &c., applying first a grease proof composition, which when dry is coated with adhesive matter, and the cork, &c., applied thereto. *Patent completed.*

655. J. DIXON and R. CLAYTON. "Improvements in rolling iron and steel for manufacturing railway wheels, and for other purposes." Dated March 15, 1859.

The object here is the manufacturing of railway wheels with the felloe or rim wider than the spokes or arms. The invention consists in first rolling bars that are parallel in width but of unequal thickness,

that is to say, the part of the bar required to form the rim being thicker than the part for the spokes; the bars thus rolled are cut off to the required lengths, and then passed sideways through a pair of rolls, the action of which expands or widens the thicker part forming the rim, and leaves that part forming the spokes untouched; or if the spokes require to be tapered sideways, the rolls act slightly on the thinner parts to expand or widen them also. *Patent completed.*

656. G. SEYMOUR. "Improvements in making refined sugar, and making potash and soda from the residues." (A communication.) Dated March 16, 1859.

The inventor obtains the juice of the cane or raw sugar, or the juice or syrup from the beet root, &c., in the usual manner, which he treats with a preparation of baryta, called caustic baryta; or he treats it with the sulphuret of barium. He makes use of certain new and improved apparatus for the fabrication of such refined sugar, which apparatus, and the manner of using the same, are not described apart from the drawings. *Patent completed.*

657. W. ROBERTSON and J. G. ORCHAR. "Improvements in weaving." Dated March 16, 1859.

This relates to the "take-up motion" of looms, and consists in the use of a pike, roller, or beam studded with pointed projections or pins for taking up the cloth, the drag or quadrant uptake being applied to, or fitted up in connection with, this pike or pin roller, which apparatus can be so adjusted as to give the exact number of weft shots in the cloth that are required, whilst at the same time it provides that there shall be no take-up when the shuttle in action ceases to give off any weft. A separate and distinct roller is employed for receiving and taking on the woven cloth, so that as the studded roller to which the quadrant is applied always remains at its normal diameter, the quadrant can be trimmed or adjusted at the commencement of a piece of cloth to work steadily and evenly to the end thereof. The details of the invention are too voluminous to be quoted here. *Patent completed.*

658. C. PARKER. "Improvements in looms for weaving." Dated March 16, 1859.

This consists in a method of arranging and working looms, so that the warp threads may be slackened just prior to and during the formation of the shed, and again tightened for the beat up. *Patent abandoned.*

659. J. PARKER. "Improvements in lever-sails, and in submerged feathering-propellers." Dated March 16, 1859.

The nature of the first part of this invention consists in multiplying the power produced by the pressure of the wind by receiving the same upon direct acting lever sails, by which term is meant sails placed upon arms attached to a central shaft similar to the arms of an ordinary water wheel, so that the portions of the sails exposed to the wind (when the vessel is sailing in the wind's eye), recede directly from the wind, the other portions of the sails being protected from the wind by a curved screen inclining to, and directing the wind upon that portion of the sails not protected by the screen. The inventor multiplies the power obtained from the central shaft, by so connecting that shaft with the driving shaft of the propeller that the latter shaft shall revolve more or less slowly than the former, according to the leverage or power desired to be obtained. The submerged feathering propeller consists of two wheels fastened to two separate shafts, placed parallel to, and at a convenient distance from each other in an air channel or trough formed in the bottom of the vessel, the ends of the shaft passing through the sides of the trough, and the wheels being so placed in the trough that their circumference projects below the trough into the water. An endless chain with paddle floats attached thereto passes round the wheels, so that the floats travel between the wheels in a straight line. *Patent abandoned.*

660. I. ASH. "Improvements in the construction of locks and latches." Dated March 16, 1859.

This invention is not described apart from the drawings. *Patent completed.*

661. F. MORDAN. "A means of keeping a stopper connected with a bottle, jar, or such like receptacle, when removed from the mouth thereof." Dated March 16, 1859.

The inventor connects a piece of elastic material to the neck of, or otherwise conveniently to, the bottle, jar, &c., and he likewise attaches it to the stopper. *Patent abandoned.*

662. H. AMBLER. "Improvements in breech-loading ordnance, and in the means of producing part or parts thereof, which improvements are also applicable to what are called small arms." Dated March 16, 1859.

The patentee forms the moveable breech of a spherical form, and of strength much in excess of that given to the barrel. The breech is bored to contain shot and powder, and the powder chamber, which is by preference in the centre of the breech, he forms larger than the bore for the shot. The bore may be grooved or rifled. The breech is at the junction, with the barrel of the gun ground to fit tightly to it, and when the gun is otherwise formed of iron, the rubbing surfaces in contact, or one of them, may be formed of brass, copper, or other metal not so liable to corrosion, and the breech is connected to the barrel by strong links with screws or other suitable means to admit of such breech turning on its axis of motion for loading, and then of being brought tight up to the gun. *Patent completed.*

663. J. FULLER. "Improvements in churns." Dated March 16, 1859.

Here a revolving axis is formed with a series of arms or heaters, which are placed around such axis, so as to succeed each other step by step, and they are each formed inclined towards their opposite edges, by which in the rotary motion of the axis the cream will be forced downwards. *Patent abandoned.*

664. W. AVERY. "Improvements in machinery for the manufacture of screws." Dated March 16, 1859.

This relates, 1, to the means of feeding the blanks into the holding clamps or jaws, whereby they are held while the head is being turned and while the thread is being cut thereon; 2, to arrangements of machinery for slotting or cutting the nick in the heads of screws, or blanks intended to form screws. *Patent completed.*

665. J. MICHEL-DENYS. "Certain improvements in the construction of railway crossings." Dated March 16, 1859.

This consists in the use of a cast-iron table or plate having lugs cast thereupon, by which it may be bolted to the ordinary wooden sleepers. Upon the top of this table are three wrought-iron crossing pieces, their upper faces being formed similar to the ordinary rail, but are made taper or conical at their lower extremity. These three crossing pieces are securely held in their places by a wrought-iron or steel plate fixed between them, being formed taper or dovetail at the edges, and secured by bolts to the top of the cast-iron table. *Patent abandoned.*

666. E. ANSCOMBE. "An apparatus for taking an accurate delineation of any view or object in open air or otherwise." Dated March 16, 1859.

This invention is not described apart from the drawings. *Patent completed.*

667. J. HARRIS, jun. "A new and useful or improved carpet sweeper." Dated March 16, 1859.

This invention is not described in detail apart from the drawings. *Patent abandoned.*

668. J. CLARK. "Improvements in the manufacture of fabrics in which compounds containing india-rubber are used." Dated March 16, 1859.

This consists, 1, in an expeditious mode of coating the surfaces of fabrics with compounds containing india-rubber, by laying on a series of coatings one on the other in immediate succession, and in the same machine. 2, In producing an endless fabric suitable for calico printers and other purposes. 3, In combining india-rubber with powdered cork and sulphur, adding when necessary india-rubber solvent, and in causing this material to be rolled or spread in sheets, or in moulding it into various shapes, and submitting it to heat to vulcanise the same. 4, In applying an endless elastic cloth or fabric to spreading or coating machines, so as to form a soft elastic bed for the fabric during its passage through the machine. 5, In combining the fibres of silk, cotton, wool, flax, &c., with woven, felted or other fabrics, so as to produce in a continuous manner combined fabric of great use and ornament. 6, In vulcanising the fabric known as "Clark's Patent Felt" by combining sulphur with the india-rubber composition used in the manufacture of the patent felt, and submitting the patent felt to the action of heat to effect the vulcanising process. *Patent completed.*

669. G. HAMILTON and W. H. NASH. "Improvements in tumbler or lever locks, and in keys for such and other locks." Dated March 16, 1859.

To avoid the use of springs for disengaging the tumblers or levers after the bolt of the lock has been shot, a projection is formed in the plate attached to the bolt, and this projection, after the bolt has been moved sufficiently to free the tumblers or levers, is, by the further movement of the bolt, caused to strike against one tooth of a cogged wheel with three teeth, or a triangular or other suitably shaped piece, which turns on centres at its two ends. This piece is thus made partially to revolve, and in revolving, one of its

edges or angles strikes against projections on the tumblers or levers, and disarranges them, and when the bolt is drawn back another projection on the plate attached to the bolt moves the rotating piece into a suitable position for its being again acted on (when the bolt is again shot forward) by the first-mentioned projection in the plate attached to the bolt. It also consists in so constructing tumbler or lever locks that the key when turned shall first act on the levers or tumblers so as to arrange them suitably for the bolt to be shot, and that after the bolt has been shot the key shall again act on the levers or tumblers so as to disarrange them before the key can be withdrawn from the lock. The whole length of the stem of the key is hollow. *Patent abandoned.*

670. H. BESSEMER. "Improvements in the manufacture of crank axles." Dated March 16, 1859.

The patentee claims, 1, the manner of forming locomotive and other crank axles from a plain slab, or rolled, or hammered ingot of cast malleable iron, cast-steel, or cast semi-steel, by sawing or otherwise cutting away such parts of the mass as will leave a piece of metal having the general form of the intended crank axle. 2, The use of circular or other saws for shaping a mass, or for cutting away the superfluous portions from a mass of cast malleable iron, cast-steel or steel, or cast semi-steel, while the same is in a heated state, in order to obtain from the mass of metal so cut or shaped a locomotive or other crank axle. 3, In the manufacture of locomotive and other crank axles made of cast malleable iron, or cast-steel, or cast semi-steel, the twisting of the axle so as to alter the angle of the different throws from the common plane in which they are formed into any desired angle or relative position to each. *Patent completed.*

671. T. W. MILLER. "Improvements in blocking or securing ships and other vessels whilst being removed, examined, or repaired." Dated March 16, 1859.

This relates to the application of hydraulic or hydrostatic power or fluid pressure employed in a series of presses or cylinders and rams fitted upon the moveable cradles or platforms of hauling up ships or shipways; or to pontoons, rafts, floating or dry docks, the ram-heads or piston-heads of which may be fitted with beams, cross-heads, or vibrating arms or levers capable of adjustment to the form or angle of the ship's side or bottom, and such arms may be filled with friction rollers, or be so formed as to act as buffers. *Patent completed.*

672. C. DEFRIES. "Improvements in lamps." Dated March 17, 1859.

This invention is not described apart from the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 26, 1859.

1739. D. B. Hale. A new and useful garment for ladies' wear, being a combined waist or body and a skirt supporter and bustle. (Partly a communication.)

Dated Sept. 5, 1859.

2024. J. B. H. H. R. Barre and J. B. M. E. Barre. Improvements in cutting out or engraving metals and their alloys.

Dated Sept. 9, 1859.

2058. M. M. Jackson. Improvements in generating steam for condensing engines.

Dated Sept. 13, 1859.

2086. E. A. F. Lebourgeois. An improved machine for providing with pin points the blocks employed for surface printing on calico, paper, or other similar materials.

2088. A. B. Freeland. Improvements in preparing hay and clover for food for horses and other animals.

Dated Sept. 14, 1859.

2092. J. Marritt. An improved double-action rotating harrow.

2094. R. C. Rapier. Improvements in the construction of steam boilers.

2096. N. Defries. Improvements in gas meters.

2098. A. Applegath. Improvements in machinery for printing and for cutting printed paper into sheets.

Dated Sept. 15, 1859.

2100. J. Addenbrooke. An apparatus for wrapping, folding, or packing up goods or parcels.

2103. J. T. Wood. Improvements in printing and embossing dies.

2104. J. P. Clarke. Improvements in the manufacture of spools or reels for the winding on of cotton, linen, thread, silk, or other fibrous materials.

Dated Sept. 10, 1859.

2100. J. Bottomley and A. H. Martin. Improvements in means or apparatus employed in weaving.

2108. B. Lauth. Improvements in the manufacture of rails for railways.

2112. J. Beck. Improvements in stereoscopes.

Dated Sept. 17, 1859.

2114. J. Luis. Improvements in mechanical hammers. (A communication.)

2116. J. Luis. An automaton bell for the prevention of collisions at sea. (A communication.)

2118. J. Luis. Improvements in cooling apparatus for liquids, especially beer. (A communication.)

2120. J. J. Kerr. Improvements in the manufacture of cartridges containing shot.

Dated Sept. 19, 1859.

2124. E. H. Taylor. Improvements in the mode of securing the bolts in fish joint and other fastenings for rails on railways.

2126. J. Hawkins and C. Hawkins. Improvements in fly presses to be worked by steam, water, or other power.

2128. R. McCall. Improvements in obtaining precipitates of copper, parts of which improvements are applicable to the production of yellow ochre.

2130. T. C. Eastwood. Improvements in means or apparatus for preparing and combing wool, cotton, and other fibres.

2134. W. Clark. Certain improvements in electromagnetic telegraphs. (A communication.)

2136. J. Court. Improvements applicable to gas and other lamps and lights, and also gas stoves for effecting more complete combustion therein.

Dated Sept. 20, 1859.

2140. W. McIlwraith. Improvements in weaving.

2142. A. Lamb. An improved method of heating the feed water for boilers.

Dated Sept. 22, 1859.

2155. T. Field. A new means and system for cleaning, ironing, pressing, and glazing women's stays, corsets, supporting bands, men's jackets, coats, trousers, and waistcoats, chintzes, laundry work (that is to say, goods and articles generally washed by laundresses), window blinds and textile fabrics generally.

2157. J. Dales. Improvements in purifying sewage and other impure waters, and in separating therefrom materials suitable for use as manure, and also the preparation of a substance to be employed for such purposes.

Dated Sept. 23, 1859.

2159. L. Castelain and C. F. Vasserot. A novel application of a plant to the manufacture of pulp for paper and millboard, and in the method of treating the same when so applied.

2161. C. J. Parry. Improvements in diamond shirt fronts.

Dated Sept. 24, 1859.

2163. J. J. Bourcart. Improvements in machinery or apparatus for opening, cleaning, carding, and drawing cotton, and other fibrous materials.

2165. A. R. Normandy. Improvements in the application of steam for cooking food.

2167. C. Lambert. Improvements in machines or apparatus for cutting and pulping food for cattle, and for other like purposes.

2169. T. Robinson. Improvements in steam hammers.

2171. J. T. Pope. Improvements in the manufacture of marbles.

2173. J. Opie. Improvements in instruments or apparatus for charging holes in blasting operations, parts of which are also applicable for like purposes.

Dated Sept. 26, 1859.

2175. R. W. Sievier. Improvements in the means of creating a draught, so as to remove the gases which may be produced by combustion, or from places where gases may be generated where they may be detrimental to health.

2177. D. White. Increasing the illuminating and heating powers of gases, and regulating the flow of gases, and improvement in the material for gas meters, and improvement in glass and cylinder holders.

2179. J. Villet-Collignon and L. George. Improvements in the typography.

Dated Sept. 27, 1859.

2181. W. Airey and J. Clayton. Improvements in machinery or apparatus for preparing silk, wool, cotton, flax, or other fibrous substances for spinning.

2183. T. Birtwell and R. Marshall. An improved arrangement of apparatus to facilitate the putting on of boots to the feet.

2185. J. S. Parfitt. An improved machine for heading bolts, rivets, screws, and other similar articles requiring to be headed whilst hot.

2187. T. Beards. Improvements in ploughing and cultivating land by steam power, and in machinery used for such purposes.

Dated Sept. 28, 1859.

2198. W. Maltby. An improved mode of producing starch-gum.

2191. E. K. Dutton. Certain improvements in "governors," particularly adapted to steam-engines.

2193. T. Sutton. Improvements in the construction of apparatus for taking photographic pictures, consisting of and entitled, "an improved panoramic lens for taking photographic pictures."

2195. W. H. Phillips. Improvements in apparatus for generating and regulating heat, applicable to culinary and other purposes.

2197. G. Evans and E. Huxley. Improvements in the construction of hernial trusses and pads adapted to surgical purposes generally.

2199. M. L. J. Lavater. Improvements in apparatus known as injection bottles, and in pneumatic discs used in apparatus for adhering to glass and other impermeable substances.

2201. D. Stewart. Improvements in presses used for pressing goods.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Oct. 11, 1859.)

1450. T. W. Jones. Stereoscope glasses.

1450. T. Cattell. Varnish and lacker.

1471. W. Clark. Supplying furnaces with hot air. (A communication.)

1483. A. V. Newton. Steam boilers.

1491. W. E. Newton. Shears. (A communication.)

1561. J. J. Griffin. Gas furnaces.

1577. M. Bogg. Washing machines.

1773. P. M. Parsons. Switches and crossings.

1847. W. MacLellan. Permanent way. (A communication.)

1923. W. Hollins and F. Hyde. Looms.

1978. J. Cowgill and J. Stocks. Spinning.

1991. R. Beverley. Wet gas meters.

2092. J. Marriott. Harrow.

2100. J. Bottomley and A. H. Martin. Weaving.

2129. J. Wright. Carriages. (A communication.)

2140. W. McIlwraith. Weaving.

2193. T. Sutton. Panoramic lens.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Scaled Oct. 7, 1859.

866. A. Chaplin.

878. W. Campion.

877. M. Wheelton.

879. M. A. F. Mennons.

881. W. Hooper.

882. W. Hooper.

888. T. Barnett, H. T.

Sourbuts, and W. Loynd.

890. J. Hawkins.

893. J. Martin.

905. W. Rowan.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 21, 1859.

ROBERT STEPHENSON.

ROBERT STEPHENSON is dead. He died on Wednesday, October the 12th. We saw him last in the House of Commons a few days before the prorogation. He then seemed to be in good health, and we had no intimation that his health had failed until a paragraph in the morning papers startled us with the painful intelligence that he was hopelessly ill. Mr. Stephenson's age was 56, and from his appearance we judged that he might live at least another dozen years; but Mr. Stephenson has lived every day of his life. He worked very hard when he was a boy, and when he came to man's estate he entered upon a career of mental and bodily labour which very few have been called to endure; and all this, together with exposure by land and by sea, in all sorts of climates, was no doubt the cause of his premature death. The laws of nature are inexorable; drive the machine fast, and it will do more work in a given time than if it were driven slowly, but it will wear out sooner.

Mr. Robert Stephenson's family boasts not of ancient descent, nor of heraldic honours. Mr. Smiles, the biographer of George Stephenson, traces it back no further than the grandfather of Robert, who was a humble labourer, and nothing more. This grandfather, Robert Stephenson, married Mabel, the daughter of Robert Carr, dyer, at Orvington, by whom he had six children, the second of which was George Stephenson, the great engineer, and father of Robert, just deceased. Both grandfather and grandmother, though "they had very little to come and go upon," but "were sore haudden doon 'in the world," had, however, the reputation of being "very honest folk;" and there was evidently some faculty in the grandfather, for he was "a curious lover of nature, and very 'fond of romantic stories;" and it is recorded by Mr. Smiles that he would often draw round his engine fire the young people of the neighbourhood and relate to them the wonderful history of Sinbad the Sailor, and other stories drawn from his own imagination. George Stephenson entered the world under circumstances as discouraging to all hopes of rising as could well be imagined. His parents were far too poor to send him to school, and therefore in his earliest days he used to run wild about the roads, go birds'-nesting, run errands, or keep the younger children out of the way of coal-waggons. At eight years old he was set to work as a cow-boy at two-pence a-day wages; afterwards he was promoted to lead horses at plough; then he was set to turnip hoeing, and at length he got to the top-most height of his childish ambition, by obtaining employment in a colliery; and subsequently, when it was announced to him that he was to have 12s. per week, so low then were his aims, and so little did he dream of the glorious career which was before him, that he exclaimed triumphantly to his fellow-workmen, "There, now, I am a made man for life." At this time he could not read or write. He did not attain to the accomplishment of reading until he was eighteen years old, and it was not till a year afterwards that he could write his own name. When he was twenty he rose to be "brakesman" at Dolly Pit Colliery, Black Callerton; his earnings then were 20s. a-week. At twenty-one he boldly took a wife. He had for some time before contemplated this step, and to prepare for it had employed his leisure hours in extra work. His

principal employment was to make and mend shoes, an art which he had learned, as he learned everything that he knew during his life, without formal instruction. His wife was Fanny Henderson, a servant in a neighbouring farmhouse. The marriage took place on the 28th of Nov., 1802; on the 16th December, 1803, ROBERT STEPHENSON WAS BORN, and in the following year the mother died.

It was a mad world when Robert Stephenson stepped into it. A more frightful epoch of its history England has scarcely ever known. We had just declared war with France; there was also war in India; bread was frightfully dear; every seventh person in the kingdom was a pauper; there was an income-tax of five per cent., soon to be raised to ten; and within a few years of Robert Stephenson's birth the country from one end to another was an armed camp. In 1805 the gross forces of the United Kingdom amounted to 700,000 men, and in 1808, 200,000 local militia were added. All this bore heavily upon all classes, and George Stephenson did not escape, for in addition to the common burdens of taxation, and the dearth of food which he had to bear, he was drawn for the militia, and had to decide whether he should serve or find a substitute. He chose the latter alternative, but the penalty was the sweeping away of nearly all his hard-earned savings. This was a terrible blow, and he felt it so severely that he "wept bitterly," and made up his mind to emigrate to America. Happily, however, for England and himself, he was obliged to give up the project, for he had no money. George Stephenson was not, however, the man to sit down in despair: having indulged his sorrow, he boldly confronted his circumstances like a brave man, and speedily conquered. About this time he went to Scotland to superintend the working of an engine at Montrose Colliery. Here he received good wages, and he returned with £28 in his pocket. During his absence his father had met with an accident and was now blind; whereupon on his return George cleared off the old man's debts, amounting to £15, placed him in a comfortable cottage, and kept him for the remainder of his life. We mention this fact for two reasons—first, to illustrate the character of Robert's father, and, secondly, to present a pretty picture. Old Mr. Stephenson, the grandfather, was very fond of his grandson, and one of his greatest pleasures was, we are told, to have a visit from his grandson Robert, who would ride straight into the cottage on his "oudy" (*Anglicè* donkey) and call upon his grandfather to admire its points, and would dilate upon its ears, fetlocks, &c., and generally finish by declaring that it was a "real blood."

Some philosophers assert that uneducated people cannot appreciate education sufficiently to strive to obtain it for their children; and, as a rule, this may be true; but if so, George Stephenson was an exception to the rule, for, from the time of his son's birth, he made up his mind that he should go to school. How he accomplished this is best told in his own words. Many years later in his life, he said:—"In the 'earlier part of my career, when Robert was a 'little boy, I saw how deficient I was in education, and I made up my mind that he should 'not labour under the same defect, but that I 'would put him to a good school, and give him 'a liberal training. I was, however, a poor man; 'and how do you think I managed? I betook 'myself to mending my neighbours' clocks and 'watches at night after my daily labour was 'done; and thus I procured the means of educating my son." And so Robert was sent to school. First he went to "a road-side school," kept by "Butter, the parish clerk," where he

learned his primer, and how to make "strokes and pot-hooks." And afterwards, in 1814, when his father had risen somewhat in the world, and could afford it, he was transferred to Bruce's Academy at Newcastle; and subsequently entered as a member of the Newcastle Literary and Philosophical Institution, the annual subscription to which was £3 3s. Nor was this all, for, as we shall see, an education at home went on *pari passu* with that at school. Some of the books of the Institution were allowed to be taken away by the members; and, on Saturday afternoon, when Robert went home to his father's, he used to take books with him, and read them to his father, when father and son would enter into lively discussions, wherefrom both gained instruction. But some books were not removeable; and from them the son was instructed to make extracts for his father's information; and his father, who had got on rapidly with his self-culture, would practice his son in reading off plans and drawings of machinery. And thus did Robert Stephenson's education go on; and with what effect, let the following incident recorded in Smiles's "Biography of George Stephenson" show:—"The son, like the father, was very fond of reducing his scientific knowledge to practice. On one occasion, after reading Franklin's description of the lightning experiments, he expended all his hoarded Saturday's pennies in purchasing half a mile of copper wire. After privily preparing a kite, he sent it up at the cottage door, fastening the wire to the palings, near which his father's pony was standing waiting for his master to mount; and, bringing the end of the wire just over the pony's crupper, so smart an electric shock was given to the animal that he was nearly knocked down. At this juncture his father issued from the door, whip in hand, and was witness to the scientific trick which had been played upon his galloway. 'Ah, you mischievous scoundrel!' cried he, and the boy ran off. But George Stephenson could not help inwardly chuckling with pride, nevertheless, at his son's successful experiment. At a subsequent period, Robert brought home 'Ferguson's Astromony;' and, under his father's direction, drew out on paper a sun-dial suitable for the latitude of the place; and, a stone having been procured, after much thought and labour, the dial was fixed over the cottage door, to the great wonderment of the villagers; and there it stands now.

Robert Stephenson stopped at Bruce's Academy four years; and, on leaving it in 1818, he was apprenticed to Nicholas Wood, at Killingworth, to learn the business of a colliery; for at that time George Stephenson had no higher views for his son than that he should get a situation in a colliery. Robert served in the capacity of under-viewer for three years, and thus became familiar with all the departments of underground work. This occupation was not unattended with danger; and, on one occasion, Robert Stephenson's career was very nearly being abruptly closed. It appears that Mr. Wood, Robert, and a man named Moodie were proceeding along one of the galleries. Robert had a "Geordie lamp" (a safety lamp invented by his father), and Wood a naked candle in his hand. When they were at the further end of the gallery, an explosion of fire-damp took place; and instantly the whole party were blown down, and the lights extinguished. They were a mile from the shaft, and quite in the dark. Robert and Moodie at the first impulse ran back; but they had not gone far, when Moodie halted, and cried out, "Stop, laddie, we maun gang back, and seek the maister!" So they went back. Happily no further explosion had taken place,

and they found "the maister" stunned, bruised, and burnt, but not dangerously injured. The time spent at the colliery was of the utmost benefit to both father and son. The evenings were generally devoted to reading and study; the two working together as co-labourers and friends. They entered into eager discussions, principally on the comparatively unknown powers of the locomotive, on which George Stephenson had already begun to reflect, and about which the son was even more enthusiastic than the father. Robert would suggest alterations, his father would offer every possible objection, proud, nevertheless, of his son's suggestions, and often warmed and excited by his son's brilliant anticipations of the ultimate triumph of the locomotive.

These discussions probably had a considerable influence in inducing Mr. Stephenson to take another step in the education of his son. The lad was only seventeen, and was doing well, and would certainly rise in his profession; but the father was not contented. He saw his own deficiencies; and probably grand ideas were looming before him relative to railroads and the powers of the locomotive, to realise which he felt that he should require more knowledge than he possessed; and he determined to give his son the best education in technical science which his means would allow; and thus secure a hearty, efficient, and generous co-worker in the elaboration of his ideas. He accordingly took Robert away from his labours in the pit in the year 1820, and sent him to the University of Edinburgh. This was a bold step, and expensive; but the father had no reason to repent it. Robert Stephenson was at Edinburgh only six months; but his mind was so prepared for the reception of knowledge that it is not too much to say that he did more in six months than many do in three years. The expense was £80; but when, at the end of the term, Robert returned with the mathematical prize, George Stephenson felt that, serious as the sum was to him then, he was more than repaid.

When Robert Stephenson returned to his home he was articulated to his father, who had already commenced manufacturing locomotives; and in 1824 we hear of him making designs for fixed engines for the Brusselton incline on the Stockton and Darlington line, then in progress. But whilst employed in the factory the health of the young engineer failed, and with the consent and encouragement of his father he took an appointment as investigator and superintendent of some silver mines in South America, whither he went in 1824. It was just before Robert embarked that his father uttered his memorable prophecy about railways: "Now, my lads," said he to his son and John Dixon as they all sat at the dinner-table, "I will tell you that I think you will live to see the day, though I may not live so long, when railroads will supersede almost all other modes of conveyance in the country—when mail coaches will go by railway, and railroads will become the great highway for the king and all his subjects. The time is coming when it will be cheaper for a working man to travel on a railway than to walk on foot," &c. This was a bold prophecy at the time; but it was soon fulfilled, and the prophet lived to see its fulfilment.

Whilst Robert Stephenson was absent his father stepped on at a gigantic pace. The Stockton and Darlington railway was made by him and opened; the Newcastle factory, begun in 1823, had been got thoroughly into work; he had surveyed the line from Manchester to Liverpool; he had fought those tremendous battles in the Parliamentary Committee Rooms with lawyers and engineers, and, almost single-

handed, had utterly routed his opponents; and having been appointed engineer of the Liverpool and Manchester line at a salary of £1,000 a-year, had commenced the works. And now, wanting help, he summoned home his son. Him he knew—him he could trust to stand by him. Robert obeyed the summons immediately, speedily arrived in England, and at once placed himself at the head of the factory, and took that burden off his father's shoulders.

And now came one of the epochs in the career of the Stephensons, and in the history of railways. During the construction of the Liverpool and Manchester line, a great battle raged upon the question whether stationary engines or locomotives should be employed in working the line. Most of the great engineers of the day, Walker, Telford, Rastrick, Tredgold, and others were against, or looked coldly upon, locomotives. George Stephenson, "aided by his son" and Mr. Locke, stood manfully his ground. The Directors, bewildered by the contrarieties of opinion expressed in the reports and rejoinders, but secretly all the while inclining to locomotives, at last hit upon the expedient of offering a prize of £500 for a locomotive that should prove itself capable of doing what was required. This was one of the turning points of the Stephensons' fame and fortune. Mr. Stephenson immediately set about the construction of his trial locomotive, the far-famed Rocket. It was erected under the immediate superintendence of his enthusiastic son. On the day of trial it was the first to be placed on the road, and not only beat all its opponents but established for ever that locomotives only were fit for railways; raised the Stephensons to the highest pitch of fame; and opened up before the astonished gaze of mankind a vista of social revolution, the end of which men of the sharpest vision were not able to discover.

Robert Stephenson was now fairly in his career, and for some years afterwards we find the names of father and son associated together in almost all the great works of the day, until gradually the father glides off the stage and leaves it to his son. In 1830 George Stephenson was appointed, in conjunction with his son, engineer-in-chief to the London and Birmingham line. But Robert took the management of this great work; he surveyed the line and prepared the plans for Parliament. In the course of this survey it is recorded that he walked over the whole distance upwards of twenty times. He also superintended the making of the line, and when in the formation of the Kilsby tunnel that hidden quicksand was discovered which was so nigh proving fatal to the work (and did prove fatal to the contractor, for he went home, took to his bed, and died), Robert Stephenson rushed to the rescue, and when all besides despaired, despaired not. The directors were for abandoning the work; but Robert Stephenson begged for another fortnight. It was granted; and at the end of that short time he had showed that he could conquer, and by the strength of 1,250 men, 200 horses, and 13 steam engines pumping night and day for eight months, and raising the almost incredible quantity of 1,800 gallons of water per minute, he emptied the tunnel and then completed the work. Robert Stephenson was also engaged as engineer to the Leicester and Warrington line; and here his scientific knowledge came into play, and he was enabled to repay his father a hundredfold for all that his education had cost. There was an estate close to the line the lease of which was for sale. This estate attracted Robert Stephenson's attention. He examined it, and decided that there was coal beneath its surface. He reported to his

father, who, after examination, bought the lease, and borings were commenced. It was then discovered that experiments had already been made by others, but without success. Nothing dismayed at this, however, Robert Stephenson went on boring. At last the trap rock was reached, but still the boring was continued, and after awhile, to the astonishment of former experimenters, the rock was perforated and coal found beneath—the trap rock had overlapped the coal stratum. We cannot notice at length all the works of this eminent man, nor is it necessary that we should do so. The early part of a great man's career is generally the most interesting, and least known. We felt that this was true relative to Robert Stephenson, and therefore we have given more space to his early life, and now can do little more than mention some of his greatest works. Newcastle owes to him its wonderful high-level bridge, which has been called "the king of railway structures." The Tubular Bridge over the Menai Straits is also his. This is erected on an entirely novel principle. Daring in the extreme it appears, and by some, when projected, it was pronounced to be chimerical. But Robert Stephenson was never chimerical. All his projects were adopted after much thought and experiment, and were based upon sound principles. Science, it has been said, teaches us what it is impossible to do; Robert Stephenson was well grounded in the science of his art, and though prepared to go to the limits of the possible, never attempted the impossible, and hence his invariable success. He also threw a bridge of the same sort over the Conway, another over the Damietta branch of the Nile, and when he died he had nearly completed an enormous structure on the same principle, nearly two miles long, over the St. Lawrence, in Canada. The problem which he had to solve before he commenced this his greatest work was a most remarkable one. From the Lachine Falls to Montreal is nine miles, and the question first to be considered was, what is the pressure of nine miles of ice four or five feet thick in a running stream of a certain velocity and breadth? And, this being ascertained, what sort of piers would withstand this pressure? These two problems our engineer has solved, for he has built a bridge that, during the four years which it has taken to build it, has been repeatedly subjected to the pressure of the ice, and has remained immovable. But we must hasten to a close. It is impossible to enumerate the works which have proceeded from the creative mind of Robert Stephenson. Suffice it to say that he has left his mark in almost every country of the civilised globe.

Robert Stephenson was Member of Parliament for Whithy. He was first returned for this borough in 1847, the year before his father died, and has only once been opposed. In politics he was a moderate Conservative. He did not often speak in the House, and when he did it was always on matters connected with his profession. About two years ago we remember that he addressed the House with great effect. There was an attempt made at a move in favour of the Suez canal project, and, of course, a good deal of nonsense was uttered; for what could the talkers know about the matter? At last Mr. Robert Stephenson rose, and the House, which just before had been all in a buzz, was now silent as a church, and every eye was turned upon the speaker; and it was amusing to note how, with a few pregnant words, he smashed the bubble. "About the political part of the subject I say nothing—but I think I know something about the professional part. I have heard a good deal about 'the fall between the two seas: well, I have

"surveyed the line; I have travelled the whole distance on foot, and I declare there is no fall. Honourable members talk about a canal. A canal is impossible—the thing would be a ditch." This was the substance of his speech; and after this, of course, there was nothing to be said—"for what can the man do that cometh after the king?" Mr. Stephenson spoke also last session with equal effect on the subject of cleansing the Serpentine. Mr. Stephenson was, of course, no orator. He never professed to be a talker: his business lay quite another way; but he could speak calmly and without hesitation, and his speeches were always marked by that clearness which indicates that the speaker understands his subject.

It is the universal testimony of all who had transactions with him that Robert Stephenson was an upright man. The career of "railway men" is a fiery ordeal, and few come out of it without scathe; but Robert Stephenson has left no "damned spot" upon his reputation for enemies maliciously to point at and friends to attempt anxiously to conceal. And he was generous as he was just. "His benevolence was unbounded," says the *Times*, "and every year he expended thousands in doing good unseen. His chief care in this way was the children of old friends who had been kind to him in early life, sending them to the best schools, and providing for them with characteristic generosity." Mr. Stephenson married in 1829 Frances, daughter of John Sanderson, merchant, London; she died in 1842. Mr. Stephenson was not again married, and he has left no children.

Mr. Robert Stephenson has received not a few marks of distinction. He was decorated with the Belgian Cross of Honour by King Leopold; in Norway he received the Grand Cross of St. Olaf; in France the Emperor, at the Exhibition of 1855, presented him with the decoration of the Legion of Honour; and Oxford, in 1857, made him a D.C.L., &c., &c. But we do not think Robert Stephenson or his father cared much for these gauds. A French lecturer said that honours were offered to Robert Stephenson by the English Government, and refused. We suppose they wanted to make him a knight. Foreigners have expressed their astonishment that Robert Stephenson was not elevated to the peerage; but foreigners do not understand English customs. We make peers of intriguing politicians, discontented statesmen, successful lawyers and generals, but if we had made a peer of Robert Stephenson, all Belgravia would have turned pale.

One reflection, and we close. Fifty-five years ago George Stephenson was a poor labourer, and Robert was lying in his cradle, while his father was cobbling shoes by his side. Then the stage coach dragged along at about six miles an hour, footpads still prowled on Hounslow Heath and Finchley Common, and a letter posted in London would reach Edinburgh perhaps in the course of a week: now we can get from London to Edinburgh in less than twelve hours, and a letter posted in the English metropolis at six p.m. is on the breakfast table of the Edinburgh merchant on the following morning; and this change has been mainly brought about by George Stephenson and his illustrious son. There are, we believe, no public monuments to these men—nor do they need any. Of each it may be said, *si monumentum queris circumspecte*.

Ere these remarks are read many of England's elect will have assembled at the tomb of Robert Stephenson and rendered their last act of homage to one of our noblest men.

It is but justice to say, that we are, to a very great extent, indebted for the materials of this sketch to Mr. Smiles's admirable volume.

THE ADMIRALTY COMMITTEE ON DOCKYARD ECONOMY.

Two months have elapsed since we gave to our readers the essence of the Report made by this Committee, and drew forth Mr. Murray's refined letter of rebuke. The blue book containing the Report is now before us, the order for printing it having been given by the House of Commons, curiously enough, on the very day that our abstract of it was put in type. As we succeeded in producing it so many weeks before the public could otherwise have had access to it, we can only regret that it should have been of such little value. It nevertheless has some claims upon our attention which must not be neglected.

In the blue book before us we have first the Report itself; then follows Mr. Chatfield's letter of dissent, and its accompanying explanations; then a reply to these by Messrs. Murray, Laws, and Bowman, and a counter reply by Mr. Chatfield; then remarks upon the whole by the Surveyor of the Navy—promises of future remarks by the Accountant-General and the Storekeeper-General of the Navy—and, finally, a reply to the Committee by Colonel Greene on the New Works Department. Most of these papers contain matters of interest, but before we enter upon their discussion we must mention the disgraceful manner in which this volume is put before the public. In the first place we find that from the table of contents with which it is prefaced no less than 90 of the 208 pages composing it are omitted altogether—nearly one-half of it. We know not who is responsible for this, but we are inclined to suspect that some sinister influence has had to do with it, inasmuch as the whole of Mr. Chatfield's crushing rejoinder to the Report is among the matter missing from the contents. The Report itself, containing only 93 pages, has more than a page and a half devoted to its contents, while all the remaining portion of the volume is dismissed with *four half-lines*! The consequence is, it is impossible to refer to the papers furnished by Sir Baldwin Walker, Mr. Chatfield, and Colonel Greene without great difficulty and trouble. In addition to this, it should be observed that Mr. Chatfield's remarks have been split up in a most confusing manner. His first paper is cloven clean in two by a letter from another gentleman, and the signature of the second portion of it is thrust in unnoticeably at the end of a table.

The first thing that strikes us on looking into the rejoinders made to the Report is, that the Surveyor of the Navy has not taken much trouble in replying to Mr. Murray. He seems to be quite content to adopt both the spirit and the substance of Mr. Chatfield's observations, and to leave his defence as that gentleman has placed it. He does not omit, however, to convey in pretty plain terms his estimate of the Committee and its designs. He tells us that he is quite aware that the object of the Committee was to get the public service assimilated to the practices of private trade, but adds that the dockyard system has been adopted deliberately, and "has stood the test of repeated and searching inquiries by Commissioners and Committees composed of men whose ability to conduct such inquiries cannot be questioned"—which is far from being the case in the present instance, being the reflection that naturally follows, of course. The Surveyor next regrets that the Committee make so many statements which are mere matters of opinion, and respecting which nothing can be proved either way, and then proceeds to impale Mr. Murray upon the horns of a very practical dilemma in the following passage, which contains its own explanation. "The insinuation,"

he says, "that measurers have a feeling of sympathy towards the men from among whom they have been selected, could scarcely have been expected from a Committee who, in speaking of the necessary qualifications for a measurer, make the following recommendation: 'In addition to the honesty and probity necessary in these officers, it is required, to prevent imposition upon them by the workmen, that they should be shrewd, active, practical men, of great experience, thoroughly acquainted with work in all its details, and also with its quality.' Where, it may be asked," says the Surveyor caustically—"where are such men to be found but in the ranks of the workmen? And yet, when selections are made from that class of men, their supposed sympathies towards the class from which they have been raised, are urged against the arrangement."

Sir Baldwin next gives his victims a sarcastic thrust, by remarking that it cannot be unobserved how frequently the same subject is taken up by the Committee "in two different points of view, to bear upon directly opposite purposes," and proceeding to give instances of this very characteristic tendency. Again, we are reminded by the Surveyor that a certain proposal of the Committee's would not be likely to be made by any one who at all understood the working of the service. Further on we meet with the remark that the importance of obtaining workmanship of the highest quality in our ships of war cannot be fully appreciated except by those who have witnessed the evil effects caused by indifferent workmanship—a very pertinent and appropriate observation. So far does the Surveyor carry this sort of thing that he appears to grow quite playful—tormentingly playful—over it: witness the following sentence: "Many of the suggestions contained in the Report are nothing more than a repetition of the every-day practices of the service, although perhaps the Committee may not be aware that such is the case." And in the same vein—"when it is borne in mind that no member who signed the Report is practically acquainted with the subject, their opinion, when unsupported by the evidence of competent persons or by unquestionable facts, must be received with that limited confidence due to opinions so formed:" and still in the same vein—"the Committee seem to imagine that the practices of private trade ought to be followed, right or wrong, suitable or unsuitable; the mere fact of private builders having adopted them seems, in the opinion of the Committee, to be a sufficient reason for their adoption in the Government yards; the only additional reason assigned is curious, namely, that Dockyards are of old standing, and therefore it is not to be expected that they will bear a comparison with private establishments of the day. This certainly is a new kind of reasoning, as experience is generally considered calculated to lead to improvement."

Having thus shown how lightly Sir Baldwin Walker has treated Mr. Murray's effort, there is nothing more to be said at present on that head. Colonel Greene, on his part, answers it much the same way. The real point at issue, in so far as the New Works Department is concerned, is, he says, this: whether every practical officer at every establishment is to have his own way, or whether the service generally is to have the benefit of the experience derived from all the establishments as centred in his office; and he adds, "the Committee being composed chiefly of local officers naturally incline to the former conclusion; but common sense and reason would support the latter." Softly, Colonel, say we. Are you

quite sure you are right in thus setting all "local officers," as such, at war with common sense and reason? We think not. We think rather that you are visiting the sins of one or two only on the heads of all. Surely it is possible for a man to be a dockyard officer without naturally feeling averse either to common sense or to reason!

The general argument of the Colonel is, however, plausible enough; (how strange it seems, by the bye, that we should have a civilian at the head of our navy, and a *Colonel* at the head of an *Admiralty* Department: but let that pass). He argues that it seldom occurs to dockyard officers—"local practical officers" he calls them, without meaning any reproach, we hope—to have to "project the particulars" of a foundry, a factory, or a workshop; seldom even of a dock, or other large work; whereas his "office" is constantly engaged in designing and constructing such works at one or other of the establishments, and consequently accumulates an amount of experience and knowledge of the details of all naval buildings such as no local officer of any length of service could possibly acquire. It is only through his office that improvements which have been adopted at any one yard can be introduced into another. Such improvements or innovations, he says, are very frequently opposed to local practices and prejudices, and it requires all, and more than all, the means at present enjoyed by his office to disseminate such improvements." The assistance of the Board of Admiralty has had to be invoked to support the views of the "office" in furtherance of "almost self-obvious improvements"—whatever they may happen to be. We have a glimpse here of the hostilities which have prevailed, as we stated some weeks since, between the Director of Works and the "practical" officers. And in the next sentence of the Colonel's hostile spirit again reveals itself: "It would be curious and instructive to compare the crude plans and suggestions which have emanated from the local officers with the well-considered structures which have been actually built." And again: "Almost everything in the way of improvement connected with this department has either emanated from, been matured in, or disseminated by, this office; yet the Committee would ignore all the experience of this office." In concluding Colonel Greene grows even yet more confident in "his office," and gives a hint to the Board of Admiralty itself on the subject. If, he says, the Board desire their work to be well and efficiently done, without any unnecessary delay—which Colonel Greene does not intend to question, surely—and if they have that confidence which they "ought to have" in his office, they should strengthen the hands of his department, "and not put it in the position of having to fight its way for every great or trifling matter with every local officer at every establishment."

We have, then, the authority of Colonel Greene himself for saying that his department is continually at war on every question that arises, whether great or trifling, with the officers of all Her Majesty's naval establishments. Surely we have here, if not a confirmation of the Committee's views, at least an evidence that changes of some kind are pressingly necessary. There is, we readily admit, much truth in the theory he propounds—that a central office for the control of Admiralty New Works ought to produce better results than could be reasonably expected from the isolated action of the officers of the separate establishments. And we further admit that Colonel Greene and Mr. Scamp have done much, very much, to promote the efficiency of our Admiralty Works.

Still it cannot be denied that an immense amount of dissatisfaction exists in the Dockyards in respect to some of the newly-constructed buildings. We ourselves receive so many complaints that we know not how to hope for any peace until something has been done to restore confidence in the "Office." Of the letters of our correspondents we have given place to only two, which appeared in our last month's numbers. But what do the writers say? "A Mechanic," of Pembroke Dockyard, states that above the new steam saw mill recently completed in that establishment a joiner's shop with a glass roof has been fitted up in which no means of ventilation were provided, and that "the place became so unbearably hot during the summer that large holes were obliged to be torn 'in the new end walls to admit a current of air.'" "A Sidelight," writing subsequently from Deptford, tells us that we "need not travel so far as Pembroke Dockyard to witness 'Colonel Greene's mania for glass roofs,' for in Deptford yard they have a similar building with a glass roof to give light and a canvas awning to keep it dark, 'the workmen preferring darkness to being baked alive.'" Near it, he says, is a store for "dry goods" with a glass roof so contrived that the upper floor is "like an oven 'when the sun shines, and like a shower-bath 'when it rains.'" He further tells us that in the victualling yard is another like structure, the oppressive heat of which in summer time caused the people to strike work and protest against it, while in the winter, snow six inches deep is often found on the floor of it. There may be, and probably is, a certain amount of exaggeration in these statements, but they could hardly have been made, much less could similar statements have been made in several quarters simultaneously, if no considerable grounds for them existed. We are quite aware that the buildings in question have been constructed with a single eye to the interests of the service, and we know further that the new joiners' shops which are so much spoken against are infinitely superior in several instances to those which they have replaced, affording facilities, as they do, for economising labour by providing for the introduction of machinery—a thing which was never in the least considered, or even thought of, in our Dockyards, to any proper extent, until Mr. Scamp exerted himself to secure its introduction. Still further, we know how easy it is to invest little oversights and errors with an imposing amount of importance when the object is to enlist the services of the Press in a war against a Government Department. But making allowances for all these things enough still remains, we think, to warrant us in asking for some species of change which shall tend to a better understanding between the New Works Office and the Dockyards, especially as Colonel Greene himself asks for the same thing—prescribing his method of accomplishing it. We must say, also, we should have been glad to see a little less of Ishmael's spirit in Colonel Greene's rejoinder. When we find a man fighting on "every matter" with "every local officer at every establishment," we cannot help suspecting there is a slight chance of his being sometimes in the wrong!

But the skirmishes of the Surveyor of the Navy and the Director of Works with the Committee have withdrawn our attention from the conflict itself. It was round the shield of Mr. Chatfield that the true battle raged, and most ably and worthily did the single-handed champion meet his adversaries. There is a great risk of our doing too little justice to Mr. Chatfield in this matter. With the Tory Government—whose purposes this Committee were to serve—gone, and with it all chance of the Report ex-

erting any direct influence, it seems of little consequence that one of the members of the Committee protested against it, and drew up an able statement by way of reply to it. But had a change of Government not occurred, an attempt would have been made to carry out Mr. Murray's recommendations, and to entail upon the country all the mischief which would inevitably have flowed from them. In that case, we should have seen the value of Mr. Chatfield's masterly rejoinder. For it is a masterly document; we have looked through it several times, and have examined much of it carefully; and, although we shall have occasion to differ from him when we come to discuss some questions which he has considered, we cannot refrain from expressing the high sense we entertain of both the professional skill and the industry which are manifested in it.

We have now, however, occupied so much space with this article, that we must defer further observations on the Report for the present. Only a close investigation of such topics as are there discussed can be of service to the country; and such an investigation must of necessity be proceeded with deliberately.

THE VENTILATION OF DWELLINGS.

It was with weighty reason and sound judgment that the Sanitary Commission lately recommended that the elements of physiology should be made, as far as possible, a part of popular education; and the wisdom shown by the Government in adopting the suggestion cannot be too highly praised. We are happy to be able to state that steps have already been taken to obtain a useful work on the above subject, free from all technicality, for the instruction of those who most need its teaching. When in conjunction with this token of progress we consider the important labours of the Association for the Promotion of Social Science, we may reasonably expect ere long to find proofs of the beneficial effects of the application of knowledge to the general well-being of the people. Science, which is now seeking its broadest field of utility, has quitted the guidance of mere intellectual ambition, to become, in the hands of the philanthropist, a mighty agency of good. It is no longer in our time to be barren, but fruitful in those results which may be seen in every home, and evidenced in the physical improvement and increased comfort of the labourer and artisan throughout the land.

The ignorance of the first conditions of animal health, as manifested in the total disregard of the necessity for the adequate ventilation of dwellings, may safely be asserted to have been productive of a greater amount of physical evil than that resulting from any similar cause. Although of more importance than the very food we eat, the supply of fresh air has been systematically excluded whenever the necessity has been felt of procuring the aid of artificial warmth. The cause of this fatal mistake is simply that the latter necessity is felt; that of fresh air, through which alone the vital heat can be sustained, is not understood. The blood becomes heavy and carbonised, the system weakened, the liver diseased, before the effect can be traced to its cause. Our winter climate is by no means of necessity less healthy than the summer. But, by the exclusion of all external air in guarding against cold, the frame becomes liable to its most dangerous effects. Whenever the imperfect construction of doors and of windows renders this exclusion impossible, a comparative degree of health prevails. Among the Irish peasantry, where this accidental cause is most active in producing ventilation,

the absence of an asphyxiating atmosphere throughout the year more than counterbalances any insufficiency of food or want of attention to cleanliness. On the other hand, where the contrivance of double windows is in use, as in Canada; or where the window is not even made to open, as in some of the mining districts of Wales, the result is found in the excessive infant mortality, the dwindled frames of the surviving children, the fading of the bloom of young women, and the pallor and failing energies even of strong men. The same result again is seen in the effects upon the appearance and strength of whole regiments of soldiers, occasioned by their close winter quarters. In Canada, men, women, and children do not look like the same persons a month after they have relinquished their winter contrivances for guarding against cold. But, to the few who attach sufficient importance to adequate ventilation, the winter of Canada is fully as healthy as the summer.

In a sanitary point of view the English open grate is a far superior contrivance to the Canadian stove—the proper disposition and management of which is a subject of such great anxiety at the commencement of the cold season in our North American colony. These stoves certainly realize a much greater amount of heat in proportion to the fuel consumed; but the advantage is lost of the imperfect ventilation afforded by the open chimney; and they are consequently more destructive of health and life. But neither in England nor America does there appear to exist the slightest inkling of the fact that the supply of air for respiration and for securing the smoke-draught may by very simple means be warmed by the fire itself. The main supply of air for the combustion of the fuel, however it may be reduced, must, under ordinary circumstances, be drawn from the exterior atmosphere through every chink and cranny; or, descending by the chimney, it fills the apartment with smoke and the gaseous products of combustion. Thus it is that the small currents of cold air, intersecting each other in every point of the confined space, are felt even in the closest atmosphere of rooms heated either by stove or by open grate. No application has ever been generally made of the obvious fact that the necessary air-supply may be drawn through pipes communicating with the external atmosphere, and heated by means of the burning fuel. The fresh air thus obtained would be both pure and warm, and would moreover replace that drawn by powerful suction through the above-mentioned chinks and crannies.

We remember assisting at an experiment the object of which was to obtain a supply of cold air during the heat of summer. For this purpose ventilating apertures were opened near the ceiling, and a metallic pipe of considerable diameter was made to communicate with the heated external air of the slated roof and to descend into the apartment. The lower portion of this pipe was then surrounded by a casing, and exposed to the effect of a freezing mixture. The result of this contrivance was a continued descent of the column of refrigerated air within the tube; forming a current which was made to impinge upon and pass through a surface kept moist by capillary attraction. By this means the temperature of the apartment was considerably reduced; but the practical advantage of the process was, for several reasons, very questionable. It is to the converse of this operation that we would specially direct the attention of our readers. The air which has become vitiated by the combustion of fuel escapes up the chimney or flue in virtue of the heat, through which its specific gravity is ren-

dered less than that of the surrounding atmosphere. To replace this stream of air which is continually abstracted by the draught of the fire is a matter which never enters into our thoughts; we leave it to replace itself without troubling ourselves as to the means whereby this is effected. A very small proportion of the total heat of the fuel is radiated into the apartment; and the remainder is expended in heating the current which escapes into the outer atmosphere. It would be easy to replace this air by the same means which occasions its discharge; and it would seem to be a very natural expedient to obtain a supply to the interior through the same agency which causes the outward draught. The discharge which takes place from the apartment through the heat of the fuel should be counterbalanced by an inward supply from the same cause. An iron pipe leading upwards from the exterior through the fuel and into the room would occasion a current to be established in either direction, and place the air which is lost and that which is admitted under similar conditions. Strange it is that hitherto our care has been to heat the former alone. The simple expedient we have pointed out suffices to fulfil the conditions of a perfect source of heat. The means for the hot-air supply need not even be visible; and this can be regulated without trouble by the ordinary ventilating contrivance.

It is more especially in the night time, when, during sleep, the animal heat requires to be sustained by wholesome respiration, and preserved by a warm atmosphere, that the evil effects resulting on the one hand from a close bedroom, and on the other by cold draughts of air into the apartment are most active. With the present means for obtaining artificial heat it is impossible wholly to escape them. Whatever course we may adopt in our endeavour to do so, is found, during the prevalence of the sudden changes of temperature to which our climate is liable, to lead to the same result. We may keep out the cold, but in so doing we inevitably weaken our powers of resisting its effects by diminishing the heat-producing function of respiration. What is peculiarly required, therefore, in our artificial sources of heat, is a self-acting contrivance by which the amount of respirable air in the apartment should be increased in proportion to the necessity for sustaining the warmth of the body. That such a contrivance is practicable and easy of attainment is sufficiently obvious; that it has hitherto been neglected, to the detriment of our health and well-being, must equally excite our surprise and our regret in realising the fact that mankind should suffer so much from causes which are within our own control, and which admit of so easy a remedy.

ON SURFACE CONDENSATION.

By J. P. JOULE, LL.D., F.R.S.*

THE author described the experiments he had made on this important subject. A peculiar arrangement he had introduced gave a very increased effect to a given surface. In this arrangement a copper spiral was placed in the water spaces. The spiral had the effect of giving the water a rotatory motion, and the water was thus compelled to travel over a larger surface than it otherwise would do. He also pointed out that he had succeeded in producing a better vacuum than the temperature of the condensing and condensed water appeared to warrant, and that thus a fresh and unexpected advantage was proved to belong to the system of surface condensation.

ON THE PERFORMANCE OF STEAM VESSELS.

By VICE-ADMIRAL MOORSOM, R.N.*

At the last Meeting of the Association at Leeds, a paper "On the Performance of Steam Vessels" was read, in which some account was given of the *Erminia*, a yacht belonging to Lord Dufferin, and I have now to present some particulars of her performance.

A return has been handed by Mr. McConnell to the "Steam Ship Performance Committee," of certain trials of the *Erminia* in Stokes Bay, on the 12th October last; and the following further particulars of that vessel and her engines will enable the members of the Association to follow me in the description I am now about to give, and to check any errors into which I may have fallen:—

Length of water-line	92.20 feet.
Breadth, extreme	22.66 "
Draught of water { F.	9.50 "
{ A.	12.90 "
Displacement, about	244 tons.
Area of greatest transverse section ..	140.18 sq. feet.
Diameter of screw	8 feet.
Pitch of do.	13 "
Length	1.84 "
Extreme breadth of each blade	3.00 "
Area of blade, about	15.5 sq. feet.
Immersion of periphery	2.5 feet.
Diameter of cylinder	15 inches.
Length of stroke	18 "
Area of fire-grate	14.124 sq. feet.
" fire-box	92.06 "
" tubes	440.92 "
" steam ports	12 x 1½ inches.
Diameter of blast pipes	4 "

The performance at the measured mile, being the mean of four trips, was as follows:—

Speed of vessel—knots	6
" screw	6.72
Slip per cent.	10.06
Revolutions per minute	52.87
Indicator horse-power by 8 diagrams	54.50
Mean pressure in boiler	51.80 lbs.
" in cylinder	32.07 "

I had written to Lord Dufferin in August, that I anticipated a speed of 6 knots from 90 horse-power, and that I had selected a *coarser* pitch than I should otherwise have preferred, in consequence of some difficulty in estimating the thrust, and that the slip might be about 21 per cent. The results show a much better performance, and I must now explain the data on which my calculations were based. The resistance of the vessel at 6 knots in smooth water was first estimated by resolving the resisting surfaces into equivalent plane surface, and deducing the specific resistance of form by an empirical application of the method of Don Gorges Juan. This gave 2763.5 lbs. It was, secondly, estimated by another empirical process, which I had found to answer within given limits of form, and was founded on Beaufoy's experiments. This gave a specific resistance of 1,896 lbs. In the absence of experiments that can be depended on for determining the thrust of the screw, I considered it safest to adopt the larger resistance, and to take as large a diameter for the screw as would admit of its being effectually immersed, so that the thrust should not be broken, and 8 feet was selected. Now, the pitch of a screw of 8 feet diameter, to produce a resultant thrust of 2763.5 lbs. at 6 knots, is 13.37 feet. The pitch selected being 13 feet, the slip to balance should be 21.11 per cent. Then, how comes the actual slip to be only 10.66 per cent.?

The answer to this is the key to the whole operation, and it is this.—The *direct* thrust of the screw under the actual circumstances of the trial was 2122.7 lbs., and the *resultant* was 1896.4 lbs., and the difference of the ratios of their square roots is 10.66. But 1896 lbs. is also the specific resistance as estimated by the second method, and as the thrust calculated by an independent process comes out the same, within half a pound, the concurrence of the two seems to establish *that* as the actual resistance at the time

* British Association, 1859.

of the trial. Such concurrence may not, however, be held to be conclusive.

Figures are said to have sometimes a singular facility in producing pleasant results. There are two modes by which these results may be tested, the one analytical, the other synthetical. I will begin with the first, and employ the other in elucidation. The effective power, or total resistance, from the actual power of 54.59 horse-power, or 1,801,470 lbs. at 6 knots, is 2961.67 lbs., which is thus distributed:—

Specific resistance	1896 lbs.
Equivalent of slip	315.67 "
Resultant of absorbed power	750 "
Total	2961.67 "

I have in this analysis, as in my former paper, classed under the general term "equivalent of slip" two distinct elements, which I must now separate. The first is, that portion of the effective power which overcomes the resistance of the water to the rotation of the blades of the screw, and which is sometimes called "lateral slip." The second is, that portion of the effective power which is employed in pushing back the water to obtain a fulcrum.

The first is.....	204 lbs.
The second is.....	111.67 "

Making together the ... 315.67 "

The absorbed power is composed of—1st, the friction of moving the machinery; 2nd, the additional friction of the load; 3rd, the back-pressure (as we are dealing with a non-condensing engine) from the blast-pipes.

For the first we have	136.92 lbs.
" second	189.60 "
" third	423.48 "

Making the total of..... 750 "

In order to give a clearer view of these elements I will reverse them and show the corresponding pressure upon the piston.

	Pressure on Piston lbs. per square inch.
Back-pressure	4.2348 ... 4.64
Additional friction of load	189.60 ... 2.07
Moving friction	136.92 ... 1.50
Resistance of water to rotation of blades.....	204.00 ... 2.23
Slip in terms of effective power.....	111.67 ... 1.23
Specific resistance of vessel	1896.00 ... 20.78

Making the totals of ... 2961.67 and 32.44

The pressure on the piston by the diagrams is 32.07 lbs., showing a difference of 0.37, which may be considered near enough. Now, if it be said that this is an arbitrary classification not resting upon known data, I reply not altogether so. I have lying before me diagrams of back-pressure from 3.45 lbs. per square inch on the piston, moving at 236 feet per minute, with a mean pressure of 67.56 lbs. to 12.3 lbs. per square inch on the piston, moving at 569 feet per minute, with a mean pressure of 65 lbs., the diameters of blast-pipes varying from 4½ to 4¼ inches, and the relations of steam ports from 14 × 1½ inches to 12½ × 1½ inches of area. The Erminia's blast-pipes were 4 inches in diameter, the steam ports 12 × 14, and the speed of piston 157 feet per minute, with a pressure of 32.07 lbs. per square inch in the cylinder. The back-pressure of 4.64 lbs. which results from the analysis is, therefore, probable, and consistent with experience. The next element of additional friction arising from the load, viz., 2.07 lbs. per square inch, is calculated upon the specific resistance of 1896 lbs., and may be disputed, because there are no satisfactory experiments on the subject. It is an estimate, and may be in excess. The next element of the pressure to move the machinery, viz., 1.5 lb. per square inch, is a little over the mean of certain trials made by my direction, of which the diagrams are before me, the maximum being 1.14 lbs. To this no reasonable exception can be taken. The resistance to the rotation of the blades, 2.23 lbs., is calculated upon the basis of

such experiments as I have access to on the friction of water on iron, and on the effective periphery of the screw. For this element, also, more precise experiments are needed, and it must be considered an estimate only. The slip, 1.22 lbs., requires no elucidation, except that it is what remains after deducting the effect of the resistance equal to the rotation of the blades. The specific resistance equal to 20.78 lbs. per square inch on the piston, or in the convertible terms of 1896 lbs. of effective power, may therefore be dealt with as a probable result, and if so, the power of the screw is needlessly in excess of any resistance the Erminia is likely to offer, and I have explained why it is so, viz., because it was designed to produce a thrust at about 21 per cent. of slip, about 50 per cent. greater than the resistance of the vessel in smooth water, which resistance, viz., 2763.5 lbs., turns out to be 45 per cent. greater than the actual resistance. Hence the screw is capable of a thrust nearly double of what the Erminia requires in smooth water. What, then, is the most suitable size and proportion of screw for this yacht? I believe it will be found that the diameter should be as large as is consistent with its being sufficiently immersed, but no larger, and that the pitch should be then such as to produce a thrust to balance the resistance under ordinary considerations at sea with a moderate slip. If the screw be 8 feet diameter, then, to produce a thrust of 1896 lbs. at 6 knots, the pitch must be 9.18 feet, and the slip about 13½ per cent. But, under ordinary conditions at sea, the resistance will be increased, and it is expedient to have a coarser pitch, in order that the thrust may balance the resistance without excessive slip. If we assume the specific resistance at a mean between the two calculated results before described, or 2329.75 lbs., the pitch must be 11.27 feet; and when the thrust works up to this resistance, the slip will be about 20 per cent.

I must now draw attention to other trials of the Erminia, viz.:—

First, on the 27th September:

Speed of vessel	6.83 knots.
" screw	7.76 "
Slip per cent.	10.75 "
No. of revolutions	60.06
Mean pressure in cylinder	45 lbs.
Indicator horse-power	87.40
Diameter of screw	8 feet.
Pitch	13 "

The results alone of this trial were sent to me, and not the particulars; and I have no means of checking them. On comparing the speed with that obtained on the 12th October—viz., 6 knots, with 54.59 horse-power—it will be found to be less than it should be—viz., 6.83 knots, instead of 7.

Second, on the 28th September:—

Speed of vessel	7.98 knots.
" screw	10.39 "
" slip per cent.	23 "
No. of revolutions	81
Mean pressure in cylinder	46 lbs. per sq. in.
Indicator horse-power	121.9
Diameter of Screw	7 feet.
Pitch	13 "

In this case, also, I was only furnished with results. The speed comes out a little beyond what it should be compared with the conditions of 12th October, viz., 7.98, instead of 7.84 knots. It will be seen that the slip is more than double of that which took place on the two trials with the 8-foot screw, on the 27th September and 12th October, and more than two per cent. greater than that which I had estimated as due to the thrust to balance the resistance of 2763.5 lbs.

In a report to the Admiralty, by Admiral Ramsay, Mr. Nasmyth, and Mr. Ward, occurs the following passage:—"All the evidence received shows that, where a ship has very fine lines, a coarse-pitched screw, with comparatively small diameter, gives the greatest speed." The language in which this proposition is couched and the condition by which it is guarded, prevent me, in the absence of the evidence on which it is founded, from saying more than that I must doubt the conclusion till I see facts in its support. It seems to

be quite at variance with the principle on which the action of the screw rests; but here is an example to bear out the proposition.

Having received some particulars of the Erminia's passage under steam from Malta to Alexandria, from the 7th to 9th of December, I may suitably introduce them here:—

Speed of vessel (mean average) ...	6.50 knots.
" Screw	9.87 "
Slip per cent.	34.20 "
No. of revolutions	77
Pressure in boiler	60 lbs.
Coal used in 45.5 hours	8 tons.

These particulars are not sufficient to justify any deductions, and mere inferences might only mislead. There is no risk of being far wrong, however, in saying that the resistance in this passage must have increased in a greater ratio than the increase of speed would account for. The diameter of the screw, 7 feet, with the original pitch of 13 feet, accounts for the slip of 34.2 per cent.—on the supposition only of an increased ratio of resistance. The next vessel to which I must invite attention is the yacht of the Duke of Sutherland, mentioned in my former paper. Full particulars of the performance of the Undine at the measured mile in the Thames, on the 6th July, 1858, in Loch-Lochy on the 27th October, and in Loch-Ness on the preceding day, have been laid before the "Steam Ship Performance Committee" by Mr. M'Connell.

The particulars of this vessel are:—

Length of water-line	126 feet.
Breadth, extreme	25 "
Draught of water	{ F. 8.6 inch. A. 11.10 "
Displacement about	294 tons.
Area of greatest transverse section	154.33 sq. feet.
Diameter of screw	7.10 inch.
Pitch, &c.	11.4 "
Length	1.4 "
Extreme breadth of blade	9.8 "
Area of blade about	13 square feet.
Immersion of periphery	1.8 inch.
Diameter of cylinder	0.24 "
Stroke	0.16 "
Area of fire-grate	45 sq. feet.
Plate surface	206 "
Tubes	820 "

The performance on the 6th July was:—

Speed of vessel	9.26 knots.
Screw	11.29 "
Slip per cent.	17.91 "
Revolutions per minute	101.74
Indicator horse-power by diagrams	157.09
Mean pressure in cylinder	lbs. per sq. in. 12.28 "
" from vacuum	10.70 "
Total pressure	22.98 "
Mean pressure in boiler	15.80 "

Now, the specific resistance of the Undine at 9.26 knots estimated as the Erminia's, by the empirical rule founded on Beaufoy's experiments, is 3809.4 lbs.

By the synthetical method it is as under, viz.:—

Moving friction	1.40 ... 342.80
Additional friction for load	1.55 ... 380.94
Resistance to rotation of blades	2.37 ... 583.50
Slip in terms of effective power	1.65 ... 405.10
Total less specific resistance	6.97 ... 1711.43
Total pressure and effective power	22.51 ... 5517
Specific resistance	15.54 ... 3805.57

The difference between 3805.57 and 3809.4 is not material in estimates such as this. It will be seen, also, that there is a difference of 0.47 lbs. per square inch in the aggregate pressure as compared with that given by the diagrams. So far the two methods are in harmony; but now I have to show a screw that is not so tractable. The direct thrust at 11.29 knots, is 7469.3 lbs., and the slip being 17.91 per cent., the resultant is 5022.3 lbs., or more than 31 per cent. greater than the resistance of the vessel. This, however, cannot be so, and the apparent excess must be accounted for.

I have already said that the screw must be sufficiently immersed, in order that its thrust may be that which is due to its diameter and pitch. What is sufficient is yet an open question. The

Erminia's was 2 feet 6 inches, the Undine's only 1 foot 8 inches. I believe this to be the explanation of the anomaly. The apparent thrust of 5022.3 lbs. was really an effective thrust of only 3805.57 lbs., in consequence of the rotation of the blade breaking up the surface of the water. This screw would produce, if sufficiently immersed, a resultant thrust of 3805.57 lbs. at 9.26 knots, with a slip of 10.32, say 10½ per cent. The actual slip was 17.91 per cent. I have found the same results in several ships of war. In all whose screws are near the surface. In none whose screws are buried.

We have now reached one of the most interesting of the investigations, which, in my former memoranda, I pointed out as worthy of the attention of the British Association. This is an investigation by experiment not difficult to accomplish, and yet I conclude it has not had the consideration of the naval authorities, as they continue to give screws to their ships, which are only immersed about one-fourth to one-eighth of their diameter, whereas the Erminia's was immersed about one-third, while the Undine's was about one-fifth. The due proportion of immersion will, I believe, be found to depend somewhat on the speed of rotation. I wish to guard myself against being misunderstood as to these estimates. They are rough approximations thrown out for the purpose of bringing to a practical issue the application of certain known laws of fluids. The application here is, as I have repeatedly declared, *purely empirical*.

It is the result of the observation and experience of one who has no theory to advance or to support, but who, as a sea officer, and as having also been actively engaged in the construction of some of the greatest public works of this country, and as being now occupied in the management of one of its largest commercial undertakings—has been in the habit of recording and classifying facts with a view to the induction of laws, and to bring within the sphere of scientific calculation what is generally determined by the sort of experience popularly called the "rule of thumb." He knows by experience that accuracy may be ensured, and time and money saved by estimates, however rough, if based on ascertained facts, as against opinions the most experienced; and he believes that the laws which govern the resistances of ships under various conditions, may be ascertained sufficiently to guard against the mistakes of which every one concerned in shipping is aware.

There are two packets plying between Holyhead and Kingston which have made that passage at the rate of nearly nineteen statute miles an hour, and their displacement is only about 600 tons. When, in 1846, those vessels were designed, though I had no responsibility in designing them, I told my colleagues that their speed might reach twenty statute miles an hour. That was not a *guess*, it was an *estimate*. It turned out, however, that the requisite length could not be given to them. One of these vessels is capable of making way against any head-sea and wind short of a hurricane. In running before the wind she is uneasy, and requires nice management. The other cannot encounter a heavy head-sea like the first, but she "scuds" with ease and comfort. A seaman will give a reason for this difference, and probably he might be right; but I doubt if he could show how a vessel is to be designed so as to unite the two best qualities of each. Yet their union is practicable; and in the records from which are compiled the returns presented to the "Steam Ship Performance Committee" are the facts which would enable a scientific naval architect to effect that union.

A question may here be asked which I am not in a condition to answer. Has the speed of ships increased in the ratio due to their increase of size? Does the speed of the *Mersey*, of 5462 tons, being about 13½ knots, with 4044 horse-power, answer to the deductions of science when compared with the *Rattler* of 1078 tons, with a speed of about 9½ knots, with 436.7 horse-power? If not, there may be reasons why not; but I have failed to discover them. I think information

on this point would be valuable to science. I had intended to make some observations on the high-pressure engines in the gun-boats, but I must postpone them for a future occasion, with this remark: That the high-pressure engines whose performance I have investigated are not fair specimens of their class; and any conclusions drawn from them, as to their suitability for ships of war, must be inconclusive.

I have felt it to be due on my part to the British Association, to bestow some pains on the matters submitted in this paper, not only as an acknowledgement of the ready attention paid to my suggestion in my absence, both last year and in Dublin, for the appointment of a committee, but also to show what may be done, and what there is to do. I trust I have shown that there is a practical issue before us worthy of the labour; that these are not the speculations of a theorist unversed in practical life, which, however amusing in the closet, can determine no actual issues, but that they have a vital bearing on questions which now exercise some of the keenest intellects of our day. The science of war has, as we all know, called forth the most practical development of the human mind. At this moment all the resources of mechanical art are stimulated to the utmost to produce, or to perfect, instruments of war. Ships are in this category. Where are the admitted laws which are to guide us? Who can point them out? I, therefore, again suggest the renewal of the powers of the committee appointed at Leeds, with some extension of their objects.

I cannot close this paper without making some attempt to discharge the debt of acknowledgement on the part of science, which I feel to be due to the two noblemen whose experiments with their yachts have enabled me to make this exposition of what I conceive to be the principle of the screw in its relation to ships. Experiment can alone prove or disprove my positions. But in either event, the Marquis of Stafford and Lord Dufferin are thankworthy, who at some cost have taken a course which *seemed to have* the sanction of science.

Experiments of this nature ought to be undertaken by Government—they, representing the nation, have the largest interest at stake, and the simplest means at command. If it should turn out that the investigation here unfolded leads to determine the relations between the *direct* thrust of the screw and its *resultant*, and between that and the form of the vessel, one more instance will be added to the many our country offers of the value of voluntary associations in stimulating individuals in the pursuit of a common object; and I shall have some satisfaction in thus vindicating the claim to be considered a scientific sea-officer, to which I once fancied I had some pretensions and to which I still attach some value. Nevertheless, I should not have gone out of my way to make public such investigations as these which have amused my leisure hours, if it had not been for the British Association for the Advancement of Science.

C. R. MOORSOM.

Highfield, August, 1859.

THE WESTMINSTER CLOCK.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—So soon as the quarter-chimes had been set going and the hands had been placed on all the dials, I thought it desirable that some efficient steps should be taken to obtain a correct rate of the clock's performance, and therefore proposed to Mr. Quarm to fix up an astronomical clock in his office, at the Houses of Parliament. To this proposal Mr. Quarm at once acceded, and cheerfully undertook the task of observing the rates.

One of the finest astronomical clocks that I have produced was consequently selected, and placed in Mr. Quarm's office on 28th September; and in order to afford additional confidence in the results, I attended personally to the fixing and adjusting of the pendulum and arc spring, &c. The whole of the adjusting did not occupy two hours, and it may be remarked that the clock at

once went to actual mean time within eight-tenths of a second a day without subsequent regulation. The next step was to ascertain by trial the degree of accuracy which Mr. Quarm was likely to attain in taking the rates; several comparisons of the first blow of the quarter chimes with the astronomical clock were consequently made by him, simultaneously with those made by myself, and the results each time were within two-tenths of a second.

These arrangements having been completed, the following rates of the Westminster clock were taken by Mr. Quarm, from the first blow of the quarters and the first blow of the hour:—

1859.	Time of Observation.	Westminster Clock Fast or Slow of Astronomical Clock.	Difference in Gain or Loss of the Westminster Clock from one observation to the next.
Sept. 29	10 30	S. ... 9.8	L. ... 0.4
"	10 45	S. ... 10.2	G. ... 6.2
"	11 0	S. ... 4.0	G. ... 0.0
"	12 0	S. ... 4.0	G. ... 1.4
"	12 15	S. ... 2.6	L. ... 7.6
"	12 30	S. ... 10.2	G. ... 5.8
"	1 0	S. ... 4.4	L. ... 8.4
"	1 30	S. ... 12.8	G. ... 0.0
"	1 45	S. ... 12.8	G. ... 8.6
"	2 0	S. ... 4.2	G. ... 1.8
"	2 15	S. ... 2.4	L. ... 7.8

"	3 30	S. ... 11.6	G. ... 8.6
"	4 30	S. ... 8.0	
Oct. 1	10 30	S. ... 11.6	G. ... 8.0
"	11 0	S. ... 3.6	L. ... 4.0
"	12 30	S. ... 7.6	G. ... 2.6
"	1 0	S. ... 5.0	

No rates were taken after this time, in consequence of the hour and quarter parts being stopped, on account of the fracture of the great bell.

It will be observed, in the foregoing table, that instead of the clock proclaiming Greenwich time within one second in 24 hours, according to the stipulated conditions, it occasionally varies more than eight seconds in a quarter of an hour.

In order to eliminate the error of the astronomical clock I have looked over several years' rates of it, taken by the late Mr. Belville, of the Greenwich Observatory, to ascertain the probable quantity, and found it to amount to rather less than two hundredths of a second for the longest interval between the observations recorded in the Westminster rates.

Besides the above, I have other rates which were previously taken by myself, with a chronometer, on Sept. 12, 13, and 23, and they show that the Westminster clock did not indicate time more accurately on those days.

In my letter, dated July 30, published in the *MECHANICS' MAGAZINE* and *Journal of the Society of Arts*, it is stated, as my settled conviction, founded on a patient and elaborate investigation of the going part, that the clock could not possibly keep time within the promised limit unless the construction were radically altered and the principle introduced which I then described. It will now be seen that the amount of error shown in the present rates more than fulfils the quantity I then prophesied.

E. T. LOSEBY.

11th October, 1859.

P.S.—To those not intimately acquainted with horology it may be explained that the arc-spring is an improvement for causing the long and short arcs of vibration of the pendulum to be performed in equal times. It was invented by me, and submitted to trials under the superintendence of the Astronomer Royal at the Greenwich Observatory, during the years 1851 and 1852, and Mr. Airy's reports thereon to the Government may be found in a Parliamentary Return to the House of Commons, No. 1006, Session, 1853.

HOW BIG BEN SHOULD BE SUSPENDED.

MR. CHARLES W. LANCASTER, of ordnance and rifle celebrity, suggests that Big Ben might with great advantage be suspended in the following manner:—The bell should be provided with a strong sphere or spherical projection at the top, and this sphere or projection should be clasped by two hollow half-spherical sockets, brought together and bolted firmly up to the supporting beams. This would provide for the bell moving and vibrating with perfect freedom, there being nothing but the friction to interfere with its motion. When thus supported the bell should be struck, not "squarely," but tangentially, or nearly so, in order that the blows of the hammer may give a very slight motion to the bell round its axis, and thus continually bring a fresh surface beneath the hammer, instead of hammering continually on the same, or nearly same, point. The annexed engraving shows one method by which the improved plan of suspension may be carried out. Mr. Lancaster considers, however, that a simple spherical recess in the upper surface of two strong and well-supported plates, at the junction thereof, would be preferable to any other arrangement.

LEE STEVENS'S PENDULOUS FIRE-BARS.

THIS invention has for its object improvements in the fire-grates of locomotive, marine, and stationary furnaces; and consists in so arranging the fire-bars that they may be free to vibrate or swing, with a pendulous motion, on their points of support, where motion is given to them by the oscillation of locomotives or the rolling of steam vessels, and to facilitate the clearing away of clinkers, casually formed in stationary furnaces, with an ordinary pricker.

Figure 1 is a side view of part of a pendulous fire-bar, and also shows a transverse section of the cross-bearer; Fig. 2 is an end view of two similar bars and a side view of a portion of the cross bearer; and Fig. 3 is a plan of such bars and cross-bearers. Figs. 4 and 5 give side views and sections of another modification. *aaa* fire-bars; *bbb* cross-bearing bars; *ccc* points of vibrating suspension. Besides the above, there are hollow fire-bars described in the specification, which can be cheaply made of ordinary plate iron, or still thinner steel plates, of probably not more than one-third the weight of solid wrought or cast iron.

The pendulous action inherent to these arrangements of fire-bars is too obvious to require any explanation; the leading feature being the avoidance of all reciprocating, rotary, or other complex machinery, to produce the desired effect, and consequent upon the trials to which the invention has been already subjected, the following are said by the inventor to be its ascertained advantages:—

LEE STEVENS'S PENDULOUS FIRE-BARS.

"1st. Greater durability for every purpose, in the ratio of at least 3 to 1. 2nd. Increased steam and economy of fuel; better combustion being caused by the uniform distribution of draught throughout the fire. 3rd. Ease of removal and replacement, each bar being independently separate from its fellows; instead of their being bound together, as the common bars are, by rectangular shoulders which virtually form dead plates from side to side of the furnace, immovable in themselves and obstructive to the passage of air. 4th. Entire avoidance of clinkering in the fire-boxes of locomotives, and for marine purposes, consequent upon the vibratory action given to the bars by the oscillation of the first and the rolling motion of the second; with the least possible adhesion of clinkers to them even in the stationary furnaces. In the latter, as the pendulous fire-bars yield readily to the pricker, either above or below their points of suspension, they facilitate its use, and enable the stoker to clean his fires in one-fourth the usual time."

An express coal-burning locomotive has been running daily with a set of the pendulous fire-bars fitted nearly four months since, without any deterioration to them, although we understand within a similar period three sets of wrought iron bars would have been expended. During the journey of this locomotive of upwards of 250 miles, out and home, the bars by their pendulous motion keep quite clear of clinkers; whilst the more perfect combustion of the fuel, from the better and more uniform draught caused by their peculiarity of form and action, gets up and maintains steam more freely, and reduces the consumption of coal. In the other instance, at works belonging to Government, four stationary furnaces in which the pendulous bars have been severely tested for several months, are occasionally cleared with a common pricker in the time usually occupied in clearing one; and in which the advantages of uniformity of draught are equally perceptible.

SIR W. ARMSTRONG'S RIFLED 32-POUNDER.

WE regret to learn that the 32-pounder gun, of the ordinary muzzle-loading service type, which was given to Sir William Armstrong to be rifled according to a new method of rifling common ordnance lately devised by him (called the "shunting groove" method), has burst in the proofs to which it has been subjected. The principle upon which it was rifled was the very ingenious one of allowing the projectile to enter and pass into the gun by grooves in which it moved freely, and causing it to pass out again on the explosion of the charge through other grooves which it fitted tightly, and which imparted rotary motion to it. We also find that in the large "Armstrong gun" lately produced by him, Sir William has considerably modified his original method of construction.

LAYING-OFF;
OR,
THE GEOMETRY OF SHIPBUILDING.

No. VIII.

The bevelling edges of canted Stern Timbers.—To obtain the shape of the "bevelling edge" of one of these timbers, we must discover the traces of a plane parallel to the moulding-edge plane, and at some convenient fixed distance from it, say the mean siding of the timber. In Figs. (28) and (29) we have reproduced the traces *B* and *B'* of the moulding-edge plane of one of the timbers given in the former diagram, together with the projections *cd*, *cd'*, and the true shape *CDU* of that edge. To find the traces of the plane of the corresponding bevelling edge, draw through the point in which the knuckle line cuts the moulding edge a plane perpendicular to the horizontal trace of the moulding-edge plane; *d'o* will be a portion of the horizontal trace of such a plane, and will also be the base of a right-angled triangle of which *d'p'* is the perpendicular, and the line intercepted between the point (*d, d'*) in the knuckle and the trace *B*, is the hypotenuse. Set off from *p'* (Fig. 28) *p'o* equal to *do* (Fig. 29), and draw *d'o*, then *d'p'o* is the right-angled triangle in question rabatted, and the angle *d'OT* is the inclination of the plane of the side of the timber to the horizontal plane. Draw from *O* perpendicular to *d'o*, *Oq* equal to the mean siding of the timber, and from *q* draw *qr* parallel to *O d'*; then set off from *o*, and perpendicular to *B* (Fig. 29), the distance *Or*, and through the point *r* draw *B₁* parallel to *B*, then *B₁* is the horizontal trace of a plane the perpendicular distance of which from the moulding-edge plane is *Oq*. To obtain the corresponding vertical trace, set off on *L T* (Fig. 28) *p's* equal to *ps*, that being the distance between the planes measured along the axis, and draw through *s', B₁'* parallel to *B'*. Having obtained these traces, we may find the projections of the bevelling edge first on the horizontal, and then on the vertical plane, just as we found those of the moulding edge. Or, we may obtain the horizontal projection by observing that the distance between the projections of the two edges, measured square to the lines *B* and *B₁*, is the same at all the level lines, and is equal to *or*. The vertical projection is found at once from this, by the simple transfer of breadths to the corresponding lines. These projections between the knuckle and level line III are (*e, h*) and (*e', h'*).

It must be observed now that in the *rabatment* the bevelling-edge plane will not turn about its own trace *B₁'*, but about the trace *B'* of the moulding edge; and we have to suppose that the two planes with the lines traced upon them are rigidly connected, and maintain their relative

FIG. 29.

positions during the revolution. Those lines which are traced upon the moulding-edge plane will fall upon the vertical plane of projection, while the bevelling edge will have to be projected upon that plane—in its true shape, however, since the planes are parallel. The effect of preserving this rigid connection will be, that if at any point the timber is square across, the two edges will coincide or cross at that point, and the distances between these edges at other points will enable us to discover the departure from the right angle or "square." Keeping this in view, let us endeavour to delineate the vertical projection, and therefore the true shape of the bevelling edge after the revolution, (e', k') being its projection before the revolution. It will be clear that in the revolution, the points in the bevelling edge, and in the trace of its plane at the knuckle and level lines, will move in lines at right angles to B' , therefore draw such lines $e' E, k' H$, &c., and for the trace $k' k_1, e' e_1$, &c.; f' , on the same level as e' , being the point to be dealt with at the knuckle, because we only know the level distance of (e, e') from the trace. We know that $e f$ (Fig. 29) is the level distance between (e, e') and the trace of the bevelling-edge plane before the revolution, and must be so after it. We know, moreover, that if we draw $s t$ (Fig. 29) at right angles to B , pt will be the level distance between the moulding-edge trace and the projection of the bevelling-edge trace after the revolution. We must therefore set off from f_1 , the new position of (f, f'), $f_1 E$ equal to $f e$. So also we must set off from k_1 the new position of (k, k'), $k_1 H$ equal to $k h$, that being the invariable level distance between (k, k') and the trace of the bevelling edge plane. Obtain similarly the points G and F , and join E, F, G , and H ; the curve so found is the true shape of the bevelling edge projected upon the moulding edge plane. To obtain from these lines the bevelling at level line II., for example, measure the shortest distance from the point I to the bevelling edge, and this will be the distance from a square in the breadth Oq ; or it will be the base of a right-angled triangle, the perpendicular of which is Oq , and of which the exterior angle between the hypotenuse and the base is the bevelling to be set off square to the moulding edge at the height of the level line. The corresponding bases for the other lines are found by measuring from Q, R , and D to the bevelling edge, the perpendicular Oq being the same in each case. All the bevellings in the timber we have taken are "standing," and very large, much larger than could be admitted in practice; from which we should infer, as we said at the outset, that the heel of the timber is too far in.

The stern above the knuckle is usually a portion of a conical surface, of which the moulding edge of the timber is a generating line. When this is so, the bevellings at and above the knuckle are all alike, and it is only necessary to obtain that at the knuckle, and as the section of that conical surface by a plane parallel to the moulding-edge plane, i.e., by the assumed bevelling-edge plane, would be a curved line which could only be determined by level lines between the knuckle and the rough tree, it has not been determined. When the timber falls upon the quarters beyond the extent of the conical surface, it will be necessary to obtain the bevellings at the harpins above the knuckle, for which purpose the same operations would have to be performed above the knuckle as have been performed below.

We may now give in general terms the rule for laying-off a canted stern timber in the way proposed.

TO LAY OFF STERN TIMBERS AS DOUBLE CANTS.

Rule.—In the half-breadth plan draw just before the knuckle a line, which we will call the *horizontal axis*, at right angles to the middle line, to determine the position of the vertical plane. Choose that one of the level planes for the horizontal plane which lies nearest to those heads of the lower timbers upon which the stern timbers are to abut, and call the corresponding line, i.e., its trace in the body, the *vertical axis*. Produce the moulding edges of the timbers in both the half-

breadth and body from the knuckle to these axes, and measure along the *vertical axis* the distances of the intersections from the middle line. Set these off in the half-breadth at right angles to the middle line to find corresponding points in the produced moulding edges. Through the points so obtained draw straight lines at such inclinations as will be consistent with good conversion, and will bring the heels of the timbers in desirable positions, remembering that where these lines cross the level line in the half-breadth corresponding to the *vertical axis* the edges of the respective timbers will also cross it. Measure the distances from the middle line at which the *horizontal axis* is crossed by these lines, and set them off from the middle line on the *vertical axis*. Draw parallel to each of the said lines in the half-breadth, and from the point in which the corresponding moulding edge crosses the rough tree, a straight line meeting the *axis*. Draw also in the body short level lines at the heights at which the moulding edges cross the rough tree, and set off upon them the distances from the middle line of the corresponding points just obtained on the *horizontal axis*. Join these new points with those related to them, and which are already set off on the *vertical axis*. These two sets of lines are those in which the planes containing the moulding sides of the timbers cut the two new planes of projection.

Thus far we have been able to deal with all the timbers together, we must now take each separately. To obtain the projection of one of the moulding edges in the half breadth set off along the *horizontal axis* the distances from the middle line in the body plan at which the intersection of its plane cuts the several level lines. Measure the shortest or perpendicular distances of these points from the intersection of the moulding-edge plane in the half-breadth, and set them off square to this intersection at the corresponding level lines. The points thus obtained are in the horizontal projection of the moulding edge.* Points in the vertical projection of the same edge may be found by transferring the breadth to the level lines in the body. From these new points in the body draw out liftings square to the intersection of the moulding-edge plane. Then on these liftings, and from points in the intersection at the heights at which the edge of the timber crosses the respective level and sheer lines, set off the distances from the *horizontal axis* of the intersection of the edge of the timber with these level and sheer lines in the half breadth, measuring parallel to the intersection of the moulding-edge plane. Join the points so found, and we have the true shape of the moulding edge.

To bevel the timber.—Draw from the projection of the moulding edge at the knuckle, a line square to the intersection of the moulding-edge plane in the half-breadth, and square to the *axis* in the body. From the foot of the line in the body set off along the *axis* the length of the line in the half-breadth, and draw the third side of the triangle of which these form two sides. From the foot of this third side, and square to it, set off the thickness of the timber, and draw to the *axis* a line from the point so found parallel to the third side of the triangle. Measure the portion of the *axis* intercepted between this last line and the foot of the third side of the triangle. Then draw in the half-breadth a line parallel to the intersection of the plane of the moulding edge, and at this perpendicular distance from it. This line will be the intersection of the plane of the bevelling edge. This same distance being also set off at the knuckle and level lines, from the horizontal projection of the moulding edge, and square to the intersections of the planes, will give points in the projection of the bevelling edge. Transfer these to the body and draw out liftings from them

square to the intersection of the plane of the moulding edge. Then set off from this intersection and along the *axis* the two distances between the intersections of the moulding and bevelling-edge planes, one measured along the *horizontal axis* and the other square to the intersections. Draw lines through these points parallel to the intersection. Square in from the outer to the inner of these lines the points in the former, which are at the heights at which the projection of the bevelling edge crosses the knuckle and level lines. From the points thus found on the inner line set off on the liftings the distances from the *axis* of the horizontal projection of the bevelling edge at the knuckle and level lines, measured parallel to the intersections of the planes of the sides. By joining these points the shape of the bevelling edge below the knuckle is obtained. If the sides of the timber lead up to the apex of the cone, all the bevellings above the knuckle will be the same as that at the knuckle, because the two outer edges of the timber are in one plane, or, viewing it in another way, because the moulding edge of the timber lies in a tangent plane to the surface.

Literature.

A Practical Treatise on the Manufacture and Distribution of Coal-Gas, its Introduction and Present Improvement. Illustrated by Engravings from Working Drawings, with General Estimates. By SAMUEL CLEGG, Jun., M. Inst. C.E., F.G.S. Third edition, greatly enlarged, and with numerous additional Illustrations. London: John Weale, 59 High Holborn. 1859.

It affords us pleasure to find that this standard work on coal-gas, by the late Mr. Clegg, has suffered nothing in this its third edition from the decease of the author. The present volume has been remodelled and considerably extended, with the view of bringing its information down to the present period, by gentlemen very competent to perform the task. We must say, however, it is scarcely as complete as it should be. We ought in a work like this to have seen some mention, at least, made of such apparatuses as Chadwick and Frost's gas meter, Hart's regulating burner, &c. Where so many modern improvements are recorded, these should not have been altogether omitted.

The Principles and Practice of Harmonious Colouring, in Oil, Water, and Photographic Colours, especially as applied to Photographs on Paper, Glass, and Silver-Plate. By an ARTIST-PHOTOGRAPHER. Second Edition. London: W. Kent and Co., 61 and 62 Paternoster-row; and J. Newman, 24 Soho-square. 1859.

THIS is a very useful and able book. The author is master of his subject, and writes exceedingly well. His publishers have seconded his efforts by getting the little volume up in a very neat and tasteful manner. Its price is marvellously low.

Remarks on Coinage: with an Explanation of a Decimal Coinage proposed to be introduced into this country. By "JACIA." London: Simpkin, Marshall, and Co. Birmingham: R. Mathison, 71 Elgbaston-street. 1859.

It has been stated in these pages on several occasions that the decimal system has not yet been fairly placed before the public, and that partisanship has much interfered with a fair consideration of the subject. Those opinions we are prepared to re-assert, and we hail, therefore, with much satisfaction the appearance of a pamphlet which, setting aside some lame attempts at wit at the expense of other advocates of decimalisation of coinage, appears dispassionately to consider the whole question, and to set forth a new proposition. The writer of "Remarks on Coinage," &c, seems to have given a considerable amount of attention to the subject upon which he descants, and there is little doubt that he has mastered many of its difficulties. He alludes to the simplicity of the decimal system of accounts, and very properly remarks upon the saving of time which would of necessity be effected in schools were the rules of arithmetic worked on the decimal plan. It is certain, too, that men of

business would soon discover the advisability of adopting it entirely were they but to try it. We are aware it has been objected that by the introduction of the decimal system of account keeping, the demands for clerical assistance would be lessened, and that clerks and bookkeepers would soon be at a discount in the market. So far, however, from recognising this as an argument *against* decimalism—if we may coin a word—we adduce it as a reason for its introduction. It is rather too late in the day to object to a thing because it lessens labour and saves time, and any attempt to prove the contrary proposition would indeed be but a waste of both labour and time. All our efforts at improvement, whether in a mechanical or scientific direction, are levelled to effect the economisation of both, and it would be folly to think of doing anything else.

The author of the work in question next advances the all-important problem—how can we "graft" a decimal coinage on £ s. d. ? He refers to the systems working in France, America, and other countries, and after making some perforations therein, proceeds to propound his own plan, which he considers superior to either. "The number of subdivisions, or intermediate coins, is immaterial; but should neither be inconveniently small nor confusedly large. The highest coin should be made of gold; the lowest of copper; and the others of gold, silver, copper, or bronze, as is found most convenient." The *pound* and *mil* scheme "Jacia" condemns, because it would entail, as he considers, a loss on the holders of copper coins. "The *farthing* being found a very useful coin (?), quite low enough in value and small enough in size, has been chosen for my basis, or starting point. Including that there would be four 'leading coins,' the 'unit of account' will be worth 1,000 farthings; the next leader 100; and the third, 10. I name these from the Latin numeral adjectives, the Mille (1,000), or Millea, the Centum, (100), the Decem (10), or Denny, and the Unum (1) or farthing; these names to be in the plural, Milles, or Millesa, Centums, Decems or Deuce, and Unums; or, if preferred, the term farthing, as regards the last-named might be retained." The writer then proceeds to demonstrate the little inconvenience with which such a change might be effected, as he thinks, and the great advantage which must arise from it. Into his elaborate tabular explanations, however, space forbids us to go. It will be sufficient to say that "Jacia" gives some potent reasons for adopting his own scheme, and whilst urging a conviction of its superiority, concludes his noteworthy and clever contribution to the decimal controversy by asserting that he has "weighed the advantages and disadvantages of a decimal coinage, and found the latter to be as dust in the balance compared with the former." For ourselves, we may say that we are as strongly impressed as "Jacia" with the necessity of so great a social reform as the introduction of a good decimal system would inevitably effect, and that we are glad to find the meeting of the "INTERNATIONAL ASSOCIATION FOR OBTAINING A UNIFORM DECIMAL SYSTEM OF MEASURES, WEIGHTS, AND COINS," at Bradford, has resulted in a series of resolutions, supported by some of the leading men of the time, in favour of such a change. The "final report" of Lord Overstone, repudiated as it was by Lord Monteagle, and notoriously one-sided, ought only to excite yet further the advocates of the decimal system to renewed exertions with a view to "final" triumph. It is possible, nay, probable, that next week we may devote more time and space to the subject, aided, as the cause has been, by the elicitation of further light from the assembly of *savans* at Bradford.

LIST OF NEW BOOKS.

Barnes's Designs for Mansions, Pillars, &c. Parts II. to VI., 2s. 6d. each.
Cotton's Phthisis and the Stethoscope, 2nd edit., 3s.
Fison's Handbook of National Association of Social Science, 2s. 6d.
Harrison's Treatise on the Culture of the Vine.
Thomson's Tables of Interest, at 3, 4, 4½, and 5 per cent., 17th edit., 3s. 6d.

* By conducting the operations up to this point for all the timbers we may complete with certainty on the drawing the disposition of the stern frame in the half-breadth. In laying-off the ship subsequently, the draftsman will be able, by reversing the latter part of these proceedings, to discover the planes of the edges, and to conform to the arrangement, an advantage which the ordinary method does not possess.

ON A SUBMARINE LAMP.

By Mr. RATTIE.*

THE submarine lamp is intended chiefly for using under water, for throwing light upon objects in the beds of rivers, or in the depths of the sea, applicable for the examination of the foundation of piers and bridges, and of the hulls of vessels while afloat, also for the purpose of attracting fishes and other residents in the deep, &c.

In the construction of the submarine lamp various points had to be attended to, as essential to its success.

1. The obtaining of a powerful light by a lamp of limited dimensions and perfectly water tight.
2. Whilst adapted for using near the surface, to be capable of extending with facility, and of strength sufficient to sustain the pressure of water, when immersed to any considerable depth.
3. The entire removal of air vitiated by the flame, and introduction of air capable of supporting combustion.

These having been severally attended to, the object has been satisfactorily attained by the lamp shown.

The lamp may be made either of a globular or cylindrical form (if the former it will require to be of glass), the bottom being made of brass, with a large screwed opening for the admission of the argand burner used; on the top of the globe is a brass cap, into which is screwed a strong copper tube, in the centre of which is fixed another tube, one-fourth less in diameter, and so fixed that air may pass freely in the space between the two; the lower end of this inner tube has a trumpet-shaped termination which enters into the globe, reaching within two inches of the top of the chimney of the argand burner of the lamp. The upper ends of the tubes terminate in a sort of lantern top, which is divided into a lower and upper compartment; from the lower compartment, the larger (or upper) tube conveys the air required by the lamp for effecting combustion, while through the upper compartment is discharged by the inner or centre tube the vitiated air, as ejected from the lamp.

The principle on which the lamp is constructed and depends for action, is that arising from the discrepancy of the gravity of the two columns of air necessarily engaged, viz., the column of cold for supplying combustion, and the column of heated air ejected. And in the arrangement of the tubes, advantage is taken to foster the peculiar qualities of the respective columns; thus, the cold being made to descend by the larger and outer tube, whose surface is exposed to the action of the water, while the heated or centre column is placed immediately over the powerful burner of the lamp.

COILED ELECTRIC CABLES:

BEING "REMARKS ON THE DISCHARGE OF A COILED ELECTRIC CABLE," BY PROFESSOR W. THOMSON.†

MR. JENKIN had communicated to the author during last February, March, and April a number of experimental results regarding currents through several different electric cables coiled in the factory of Messrs. R. S. Newall and Co., at Birkenhead. Among these results were some in which a key connected with one end of a cable, of which the other end was kept connected with the earth, was removed from a battery by which a current had been kept flowing through the cable, and instantly pressed to contact with one end of the coil of a tangent galvanometer, of which the other end was kept connected with the earth. The author remarked that the deflexions recorded in these experiments were in the contrary direction to that which the true discharge of the cable would give, and at his request Mr. Jenkin repeated the experiments, watching carefully for indications of reverse currents to those which had been previously noted. It was thus found that the first effect of pressing down the key was to give the galvanometer a deflexion in the direction corresponding to the true discharged current, and

that this was quickly followed by a reverse deflexion generally greater in degree, which latter deflexion corresponded to a current in the same direction as that of the original flow through the cable. Prof. Thomson explained this second current, or false discharge, as it has since been sometimes called, by attributing it to mutual electro-magnetic induction between different portions of the coil, and anticipated that no such reversal could ever be found in a submerged cable. The effect of this induction is to produce in those parts of the coil first influenced by the motion of the key a tendency for electricity to flow in the same direction as that of the decreasing current flowing on through the remoter parts of the coil. Thus, after the first violence of the back flow, through the key and galvanometer, the remote parts of the cable begin, by their electro-magnetic induction on the near parts, to draw electricity back from the earth through the galvanometer into the cable again, and the current is once more in one and the same direction throughout the cable. The mathematical theory of this action, which is necessarily very complex, is reserved by the author for a more full communication, which he hopes before long to lay before the Royal Society.

THE GREAT EASTERN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN.—The data on which your application of the Admiralty formula to the speed and performance of the Great Eastern is founded are, I fear, imperfect. The power which drove the ship at the alleged speed of 15 knots an hour, you take at 7,200 horses. At the only time when the ship went 15 knots an hour, or near it, the sails were supplying a good deal of propelling power, in addition to the indicated steam-power of 7,200 horses.

I hope you will endeavour to have the subject well ventilated in your journal. All the facts connected with or bearing upon the performance of this ship ought to be made well known, and they ought to be thoroughly discussed.

There is no doubt but that the speed of the ship will disappoint public expectation, and there is a great danger of mystification leading many people to imagine that there is no use in making steam-ships of very large dimensions. To counteract this misapprehension it ought to be made more known than appears to be the case at present that the Great Eastern is not designed for high speed.—Mr. Brunel designed her for carrying a very large load of coal, and her great size enabled him to obtain as good a speed as that of fast smaller vessels, notwithstanding the large load of coal.

Whether the scheme be sound commercially is a separate question altogether from that of what the performance of a large vessel compared with a small one may be.

One test of the importance of a large scale in obtaining speed would be to calculate what would be the probable performance of a reduced Great Eastern.

It is to be hoped that unreasoning disappointment at the speed of the Great Eastern may not enable that active and energetic body, the proprietors of existing slow steamers, who abhor progress, to propagate the impression that large steamers are a mistake.

I want to see one upon my bosom which will carry crowds of tourists between America and Europe at the rate of at least 25 miles an hour.

Your obedient servant,

ATLANTIC.

17 October, 1859.

P.S.—What is wanted is an Atlantic ferry steamer of the length and nominal power of the Great Eastern proportioned and formed for speed; such a ship would necessarily include comfort.

[We do not believe that the sails added anything considerable to the speed of the Great Eastern. It would require an enormous spread of canvas, and a very strong breeze, to add much to the speed of a ship going at the rate of, say, 14 knots an hour.—EDS. M.M.]

GENTLEMEN.—The Great Eastern steamship is no doubt a great success in many points of view, but making every allowance for disadvantageous circumstances during the late trial, we must not attempt to conceal from ourselves that expectations have not yet, at least, been realised in regard to the superior speed which was anticipated from her fine lines and immense size. It was certainly hoped that the combination of these two elements would have inaugurated a new era of velocity in maritime conveyance. Of course I do not allude to absolute velocity, procured by an indefinite expenditure of fuel, but a velocity in relation to the power employed; and which both experience and science inform us ought to proceed in some increasing ratio with an increase of size, when accompanied with a corresponding employment of power.

No doubt if we take burden or transport capabilities into the calculation, there is not much cause for disappointment, for the formula in which the displacement of the ship is involved gives, as you observe, the high number 316 as the co-efficient of its dynamic performance; whereas Mr. Atherton assigns for the standard of high efficiency in this respect only the number 250. In this aspect, therefore, of mercantile transport in combination with speed and power, and involving therein commercial success, the Great Eastern is complete. This was to be expected from her great size and her great length in proportion to width, whereby resistance, both from the translation and the friction of water, is reduced in a ratio to burden, to a degree far beyond anything hitherto attempted. But considering her as a passenger vessel, in which, as in express trains, velocity, independent of transport, is the object exclusively valued, her performance, as yet, at least, is even inferior to what has been already accomplished. The inference is, that no great improvement is apparent as the result of form in combination with size, apart from the influence in the proportion of length to width upon that form, but which is not necessarily productive of fine lines.

The formula to test efficiency in this respect and the value of form is undoubtedly that in which we substitute the midship section for the displacement. The highest number which you give in reference to several of our war steamers is in the case of the *Miranda*, the efficiency of which is denoted by the figures 780.* Now, taking the speed of the Great Eastern at a certain period of her trial at 15 knots; her midship section at 1,588 feet; and the horse-power then developed at 7,200—in which assumption the first and last items are, according to the *Times*, too favourable—the number indicating performance is only 744; and if we knew what the Himalaya and the Persia accomplish, the comparison, it is to be feared, would be yet more unfavourable. Now, as the form is certainly not faulty, and as it can by no means be admitted that it could possibly neutralise the other proved advantages derived from proportion and size, even though it did not add thereto, we are, I think, authorised to make this further inference, that her capabilities in regard to velocity have not yet, for some cause or other, been fairly developed. This is a more probable conclusion than that other vessels have been built after a better type.

In regard, indeed, to absolute velocity, it is not at all unlikely that her speed will ultimately be 18 knots; but the scientific and economical question would still remain, whether, with such velocity, the dynamic performance in relation to the power employed would be then improved. We may expect that it will, inasmuch as with a deeper immersion the slip of the propeller—the amount of which we have not been informed—may be lessened, and the slip of the paddle-wheels, amounting now to 14 per cent., would certainly be reduced. Asking simply for information, may I inquire whether, at the best, this slip is not likely to be too great, and to be a constant needless

* This, as most of our readers doubtless inferred from the context, was a printer's error. It should have been 680.—EDS. M.M.

* Abstract of British Association Paper, 1859.

† British Association, Section A, 1859. *Athenæum*.

source of loss of velocity, seeing that the area of the twelve immersed floats is not one-third of the area of the midship section. Is this proportion in accordance with the usual practice? Would it not be well to give the floats increased depth? Does the fault lie here for deficiency of performance as determined by the midship section.

It will, however, be in stormy weather—occupying, by-the-by, a great portion of the year—that both the absolute and the economic speed will be found to be most conspicuously in favour of the Great Eastern, for a heavy sea will be no impediment comparatively to her progress. Under these circumstances her superiority to any vessel, which though in fair weather may be equal to herself in velocity, will be seen to be very great, in respect merely to speed.

I am, Gentlemen, yours,

BENJ. CHEVERTON.

[Our correspondent forgets that a very small (comparative) amount of engine-power has been given to the Great Eastern. Only newspaper writers ever taught the public to expect any very high speed from her. As to the indicated horse-power being understated in our article according to the *Times*, we admit it may have been, although 7,200 was the number given to us by one of the very few persons who had an opportunity of learning what it was—a person who would have exaggerated nothing in the ship's favour. But even if we take 7,800 horse-power—a number since put forth as the proper one—we still get 692 and 292 for the Great Eastern's constants, one of which is much higher than that of any ship of the Royal Navy, while the other is equalled by only four vessels of that navy.—Eds. *M.M.*]

CONSTRUCTION OF SCREW PROPELLERS. TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN.—Your correspondent, Mr. Hewitt, may study this subject still further with advantage to himself. In answer to his questions I would say, we do find a curve or twist imparted to the vanes of a windmill, technically called *wenthering*; and the reason of its omission in the smoke-jack and in flying-tops is, because power is abundant and economy of construction is an object. I once made a flying-top with a perfect screw form, and it was very effective; I did not attempt a comparison with others, because a fair conclusion could not be drawn, but it satisfied my then boyish philosophy, that the perfect screw was the best even for that unimportant article.

I should weary your readers if I pointed out the the disadvantages of a *flat* surface screw; they are obvious to the reflective mind, the floundering tendency being all on the side of that false construction.

A screw propeller acts upon a solid cylinder of water; the more perfect the cylinder, the better the screw is *fed*, and the less will be the vibration; but we must have a stern-post, and the stern-post must have some thickness; this interferes with the perfection of the cylinder of water, impairs the *feed* of the screw; consequently the screw at every half revolution arrives at a *vacuum*, an interruption in its fulcrum; hence it travels past the wake of the stern-post with a jerk, which communicates a tremulous motion. I believe that there is often a perfect vacuum formed abaft the stern-post, the water passing several inches aft on each side before it meets.

Griffith's screw having a large boss tends to correct the evils arising from the imperfect cylinder of water, but its *flat*, unscrewlike surface is a drawback. Its entrance into the vacuum above-mentioned being confined to so small a surface at its forward end, and its greatest diameter being well aft the stern-post, and being without radial edges, vibration is almost prevented.

I think much good may be accomplished in lessening vibration by thinning off the after edge of the stern-post as much as possible, in the same manner as you stated, some time since, the forward edge of the rudder-post has, with advantage, been

served. Of course, close to the axle it is immaterial, but above and below the centre of the propeller shaft it may be easily done.

I am, Gentlemen, your very obedient servant,

T. MOY.

Clifford's Inn, Oct. 17, 1859.

AN EXTRAORDINARY CABLE.

MESSERS. BROWN, LENOX, & Co., of Millwall, the manufacturers of anchors and cables for the Admiralty, have just completed upwards of forty fathoms of what is probably the largest cable that ever was made. It is to be used for mooring the large floating coal-ship in Malta harbour, and is of sufficient strength to hold it with a line-of-battle steam-ship lashed on each side of it, in the roughest weather. The employment of this cable will therefore enable the largest ships of war to come up to the depot and coal without casting anchor, and steam away to give place to others directly they have taken in their supplies. This facility would be very valuable in time of war. The cable is formed of $\frac{1}{4}$ inch iron, with links 27 inches long, each link weighing no less than 2 cwt. 3 qrs. On Wednesday last we attended the works and saw this enormous cable tested under the supervision of Mr. Willcocks, the master smith of H. M. Dockyard, Woolwich, Mr. G. Cotsell, the master smith of Chatham Dockyard, being also present. By an admirable arrangement of combined steam and hydraulic apparatus, devised by Mr. W. Roberts, the foreman of the works, the pressure was run up to the maximum testing strain of 187½ tons in a very few minutes, the cable sustaining it without affording even the slightest evidence that it was being subjected to such a high degree of tension. This, however satisfactory, was not surprising, inasmuch as the cable is supposed to be capable of bearing twice the test-strain without injury. The small steam engine which works the hydraulic apparatus is so arranged as to do all the heavy work of pulling the cables on to and off the testing platform, and afterwards to run them out to the wharf for shipment.

Our Weekly Gossip.

MR. ATHERTON asks to have the following letter inserted:—

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR.—It is gratifying to me that you approve of the general tenor and purport of the paper presented by me to the British Association at their late meeting at Aberdeen, and that your ideas of its public utility have induced you to insert it with editorial remarks in the *MECHANICS' MAGAZINE* of the 14th inst.; but in your thus bringing the subject of "Mercantile Steam Transport Economy as affected by the Consumption of Coals" before the notice of your readers, I regret that you have reverted, in terms which I may not altogether overlook, to our former and closed discussion on the deficiencies of our legislative system of tonnage and engine power registration, which subject has nothing to do with my present paper. In my discussions with yourself as editor of the *MECHANICS' MAGAZINE*, I have always felt that some latitude must be allowed for the necessity which constrains editors of public journals to be somewhat spicy in their dishing up of rather heavy materials for the public taste. In common, therefore, with your other readers, I enjoyed the raciness with which, though at my own expense, you excited public interest in the tonnage and horse power registration questions; but as in your present editorial remarks you again concede the great points for which I formerly contended, viz., that "builders' tonnage" and "nominal horse-power" are no measurement at all of the capability of ships to carry weight, or of the working powers of engines; that in shipping affairs the terms recognised by the legislature are repudiated by science; and as it was to expose this state of things and its consequences, in respect of which you now observe "all calculations based on this principle are delusive," that my former efforts, which you are now pleased to designate as "frantic invocations," were directed; moreover, as my papers thus designated by you as "frantic invocations," and in regard to which you now congratulate me that "a change has come over the spirit of my dream," were honoured with the medal of the

Society of Arts, and have for three successive years been received by the British Association for the Advancement of Science, and for three successive years been ordered by the Council to be inserted in full in its annual volume of its transactions—under these guarantees for the public utility and general propriety of my papers I leave it with your readers to judge of the suitableness or otherwise of the choice terms which you now address to me, and of your taste in the present application of them on my having written a paper which you do approve. Publicly and practically it is a satisfactory result of the discussion referred to that the deficiencies of our shipping and engine-power registration have been exposed, and that in consequence of this exposure shipping affairs, as respects the dynamic performances of steam-ships, are now being generally investigated with reference to displacement and indicated powers, to the exclusion of builders' tonnage and nominal horse-power, the recognition of which change has already opened people's eyes and rendered steam-ship construction subject to competitive rivalry conducive to progressive improvements, from which great public benefit will undoubtedly result.—I am, Sir,

Your very obedient servant,

CHAS. ATHERTON.

Woolwich Dockyard, 18th Oct., 1859.

Mr. Atherton is so welcome to any advantage which such a letter as the above can bring him, that we shall not take the trouble to reply to what he says in it, although we dissent—let it be understood—from several statements and implications contained in it. Any one who will take the pains to compare his first paper on shipping registration with his last will see both how necessary severity on our part was, and how beneficial it has been. Mr. Atherton seems to think that the award of a medal by the Society of Arts, and the printing of a paper or two by the British Association, are sufficient to prevent the criticism of a scientific journal from taking effect. But what nonsense this is! If Mr. Atherton should contrive to cover himself from head to foot with a perfect mail of medals, would he be thereby protected from the shafts of reason and truth? It was not, however, because of his "frantic invocations" that he had a medal awarded him; it was in spite of them, as he should have seen to see. If he will accept our advice he will let bygones be bygones, and confine himself to the good work on which he has at last fairly entered, and in which he shall have our best support.

Orders were received at Portsmouth late the week before last to fit Her Majesty's ship *Urgent* with Cunningham's patent reefing gear. In consequence of the artificers of the Dockyard having been so recently employed in getting ready the steam flotilla for China, the fitting of the yards and sails was undertaken by Mr. Cunningham. The yards were sent into the Dockyard on Monday last, completely fitted, and will be crossed so soon as the *Urgent* can get alongside the wharf.

In Mr. Moy's letter on aerial navigation in our last number, there is an error. "A hundred miles an hour would be 1,600 feet per minute." It should have been 8,800 feet per minute.

Mr. J. H. Greatrex, the well known scientific photographer of 70 Regent Street, impressed with the many lives that are yearly sacrificed by fire—in many cases, according to his notions, perfectly preventable—has completed a model by which he suggests a mode of easy escape from a house under almost the worst phases of a conflagration. The plan is simply to build to those houses already erected an outward perpendicular shaft, in which cross step-pieces as a ladder are inserted. This shaft he would communicate with each landing by swing iron fire-proof doors; and with those buildings not already erected he proposes to leave to the architect the carrying out of his patent so long as the main features of the principle are held in view. Mr. Greatrex invites the inspection of all those interested in the discovery of some really practical means of rendering our dwellings secure at least from the loss of life, and we consider that he deserves every credit and encouragement for thus devoting his practical mind to a subject so vitally important.

NOTICES.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to B. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 4d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment:—

STEAM ENGINES, &c., 728.

BOILERS and THEIR FURNACES, &c. *None*.

ROADS and VEHICLES, including railway plant and carriages, saddlery and harness, &c., 724, 727.

SHIPS and BOATS, including their fittings, 677, 703.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 693, 706, 736.

FOOD and BEVERAGES, including apparatus for preparing food for men and animals, 676, 679, 688.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 673, 684, 701, 704, 706, 721, 729.

BUILDINGS and BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 678, 696, 714.

LIGHTING, HEATING, and VENTILATING. *None*.

FURNITURE and APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 695, 699, 718, 719.

METALS, including apparatus for their manufacture, 681, 690, 691, 697, 703, 707.

CHEMISTRY and PHOTOGRAPHY *None*.

ELECTRICAL APPARATUS, 687, 716.

WARFARE, 683, 725.

LETTER PRESS PRINTING &c., 710.

MISCELLANEOUS, 674, 675, 680, 682, 683, 689, 692, 694, 698, 700, 708, 711, 712, 713, 715, 717, 720, 722, 723.

673. C. GARNETT. "Improvements in machinery for ginning cotton, and for cleaning cotton and certain other fibrous materials." Dated March 17, 1859.

This consists, 1, in a mode of securing the toothed wire to the cylinders or toothed rollers of cotton gins or other machines, and in the application of an improved clamp through which the wire passes when being wound on the roller. 2. In applying wheels and pinions to the toothed roller cotton gins for increasing the speed of the working parts when turned by hand. 3. In applying suitable self-acting agents to the hoppers of toothed roller, saw, and other cotton gins for rendering them self-feeding. 4. In applying a toothed roller cotton gin to certain opening and cleaning machines in such a position that the seeds or burrs thrown out by the beater or pricker cylinder are deposited in the hopper of the gin by which the fibres are separated from the seeds or burrs. *Patent completed.*

674. J. H. JOHNSON. "Improvements in machinery or apparatus for folding and stitching sheets of paper." (A communication.) Dated March 17, 1859.

Here the sheets to be folded are laid upon a table, above which is extended, in a horizontal position, a knife or flat blade, which in descending forces the sheet into a slot across the table, and carries it down below the table between india-rubber bands in a doubled state. A second blade in a vertical position then advances and forces the once folded sheet through a second slot which effects the second fold, and lastly a third blade, which is horizontal and at right angles to the last one, completes the third fold, and forces the folded sheet between a pair of pressing rollers, which finally deliver it at the side of the machine. When required, the stitching may be effected immediately before the final fold is made by two needles supplied with thread from a suitable holder, which is arranged to impart the requisite tension thereto. *Patent abandoned.*

675. E. T. HUGHES. "Improvements in machinery or apparatus for crushing sugar canes and other materials." (A communication.) Dated March 17, 1859.

The inventor fixes upon a platform a strong framework, having bearings for the shafts of the crushing cylinders, and also for the main driving shaft, which latter is divided in the centre and furnished with two cranks. Upon the shafts of the two lower cylinders toothed wheels are fixed in the usual manner, geared into another wheel on the top cylinder shaft, at the end of which is a large toothed wheel geared into a pinion on the driving shaft, the cranks of which are connected by rods to a double set of compound levers, which are again connected to long levers at each side or end of the apparatus. The aforesaid long levers are acted upon alternately either by hand or power, giving motion to the intermediate levers and cranks, the effect of which is transmitted by means of the

gearing to the crushing cylinders which act effectively either by the power of two men or other power. *Patent abandoned.*

676. R. A. BROOMAN. "Treating barley so as to obtain new alimentary substances therefrom." (A communication.) Dated March 17, 1859.

The inventor first sifts the barley, then pounds or crushes it between peculiarly-formed millstones, then passes it through a bolting machine, then subjects it to the action of a "ventilating" apparatus, then again pounds or crushes it as before, and finally sifts it into two, three, or more parts of as many different qualities. The object is to obtain meal from the grain in great purity. *Patent completed.*

677. T. SKELTON. "Improvements in steering apparatus." Dated March 17, 1859.

This relates, 1, to tillers, and, 2, to yokes; and the object in both cases is to avoid the slacking of the steering ropes to improve the steering. The inventor forms in the tiller a slot or a groove in which runs a roller fixed in the middle of a double block. The steering ropes are attached to this block, and lead around a steering barrel in the usual way. As the steering wheel is turned and the helm thereby moved, the roller of the block slides along in the slot or groove in the tiller, so as to prevent the necessity of the length of the rope altering. In the case of yokes the inventor modifies the plan by fitting a rolling block at the end of each arm, the action being essentially the same in both cases. *Patent abandoned.*

678. A. G. HUTCHINSON. "Improvements in counteracting damp in buildings." Dated March 17, 1859.

This consists in the use in the construction of the outer walls of buildings of bond bricks, headers, and bond stones, which are previously rendered non-conductors of damp at one end, and for any required distance down the sides thereof, by the application of any suitable damp and proof material or materials. *Patent completed.*

679. P. LAROCHEITE. "Improvements in machinery for brewing." Dated March 17, 1859.

This invention is not described apart from the drawings. *Patent completed.*

680. A. MEIN. "Improvements in making glass bottles, and in the apparatus connected therewith." Dated March 17, 1859.

The patentee uses a mould which is internally of the figure of the bottles to be made. It is split vertically so as to be capable of being opened into two halves; the part which moulds the neck and rim of the bottle points vertically downwards, and contains a hollow cone spindle or nozzle to mould the tube of the neck internally. The mould has also a cover which moulds the bottom of the bottle. The mould being shut laterally, but with the corner off, a proper quantity of glass in a soft state is placed in it; the cover is then put on by hand or by mechanism, and a blast of air is blown by suitable apparatus through the hollow spindle. This swells out the soft glass so as to make it fit the mould, and completes the formation of the bottle. The mould is then uncovered and the bottle taken out. *Patent completed.*

681. A. WARREN and W. H. TOOTH. "Improvements in the manufacture of iron." Dated March 17, 1859.

Here pig iron is melted in a reverberatory furnace in the presence of hydrogen gas, nitrogen gas, nitrous acid gas, nitric acid gas, or cyanogen gas, obtained by any suitable apparatus, and primary suitable materials, atmospheric air being excluded as much as possible from the interior of the furnace; or the requisite gases may be generated by supplying jets or streams of coal-tar or pitch to the ordinary fuel in the fire place of the reverberatory furnace. The pig iron being melted is then run out and cast into slabs, pigs, or blocks, which on being set or cold are melted and puddled in a puddling furnace. *Patent completed.*

682. J. DONAT. "Improvements in apparatus used with matches for obtaining instantaneous light." Dated March 17, 1859.

This is applicable where a length of cotton saturated with wax or stearine or other substance having phosphorus deposited upon it at intervals is used. The length of match is formed into a spiral coil and placed within a cartridge of this metal having an opening at one end through which one end of the match projects. This cartridge is placed within a metal tube, one end of which is formed conically, and at the point of the cone there is a small hole through which the end of the match is passed by means of two rollers. On the exterior of the tubular case another tube of glass metal slides, and when slid up beyond the end of the tubular case prevents the match from being blown out by the wind. *Patent abandoned.*

683. W. COOK. "A smoke consumer." Dated March 18, 1859.

This consists in constructing furnaces or fire-places

to which the same may be applied with an opening or aperture at the lower portion or base of the grate communicating with the chimney, so that the smoke, which is prevented from passing into the shaft as at present, is thereby carried downwards through the fire and consumed. *Patent abandoned.*

684. W. B. TAYLOR. "Certain improvements in or applicable to looms for weaving." Dated March 18, 1859.

This consists of apparatus for applying the dressing to the warp when in the loom. The dressing is supplied to the warp by a brush revolving in a trough, which brush delivers the dressing to a roller furnished with a doctor; the warp passes over this roller and is pressed upon by another roller covered with flannel, &c., and then through two stationary brushes. The warp on leaving the warp beam, or in any place between the warp beam and the healds, passes through one or more reeds, and it is separated by one or more lease rods to keep each warp thread distinct from the others. A fan is applied to cause a current of air to act on the warp threads to dry or partially dry them before they pass through the healds. *Patent completed.*

685. Sir W. G. ARMSTRONG. "Improvements in the means of igniting explosive projectiles." Dated March 18, 1859.

The object here is to cause a shell or projectile to be ignited and exploded on striking an object sideways, or otherwise than endways. The striker is fixed on a bolt which is withdrawn by the shock the projectile receives on the firing of the gun, and being so withdrawn is at liberty to move to one side when the shell or projectile is checked in its flight by striking sideways against an object, the effect of which motion is to break or crush the receptacle of the detonating composition, and to fire or ignite the charge on the shell or projectile falling on its side, or striking with its side instead of its end against an object. *Patent abandoned.*

686. F. PORTS. "A combined metallic support and label for training, supporting, removing, and transplanting flowers or trees, in gardens, or green and hot-houses, or for other horticultural purposes." Dated March 18, 1859.

This relates to the construction of galvanised sheet iron sticks for supporting and training flowers. In connection with such sticks a suitable flattened part at the top is employed on which the name of the plant is written. *Patent abandoned.*

687. J. MOLSWORTH. "An improvement in telegraphic communication." (A communication.) Dated March 18, 1859.

This consists, 1, in employing an entire metallic conducting circuit in combination with any known generators of galvanism, electricity, or electro-magnetism, and with any known mode of breaking and closing such circuit at pleasure, and with or without electro-magnets. 2. In using one such generator at every station for the main circuit from which intelligence is to be sent to any other station by means of the said combination, and the same is to be adjusted to the circuit and to the other aforesaid known agencies so as not to have such generator brought into action, except only when intelligence is being transmitted from such station. 3. In employing for such conducting circuit any metallic rod, wire, or cord of any sufficient conducting capacity to transmit the current so generated of the desired intensity and quantity, such wire, rod, or cord not requiring artificial insulation. 4. In employing in the circuit aforesaid any known instrument or mode of recording, marking, or printing signs or letters at each and every station desired. *Patent abandoned.*

688. R. CLEGG and R. FELL. "Improved apparatus for obtaining aerated fresh water from salt water." Dated March 18, 1859.

This apparatus is composed of five parts, viz., a generator or condenser, a vacuum chamber, an air pump, and a closet-tank. We cannot devote space to a description of the operation of the apparatus. *Patent abandoned.*

689. J. HINKS and G. WELLS. "A new or improved penholder." Dated March 18, 1859.

This consists essentially of two hollow cylinders or tubes, fitting one upon the other, the inner tube being elastic and the outer tube inelastic. There are various details included. *Patent abandoned.*

690. R. MUSHET. "A new or improved metallic alloy." Dated March 18, 1859.

This consists in melting deoxidised wolfram or deoxidised tungsten with a triple metallic compound of iron, carbon, and manganese, so as to produce by the fusion together of these substances a metallic alloy of tungsten, iron, and manganese. *Patent completed.*

691. R. MUSHET. "An improvement in the manufacture of cast steel." Dated March 18, 1859.

This consists in manufacturing cast steel by the

addition of alloy of tungsten, iron, and manganese to melted decarbonised cast iron, the said cast iron having been decarbonised by having had air passed or forced through it whilst in the melted state. *Patent completed.*

692. A. L. THIRION. "Improvements in water, wind, steam, and hand mills." Dated March 18, 1859.

This invention is not described apart from the drawings. *Patent completed.*

693. C. LAMBERT. "Improvements in corn and seed drills." Dated March 18, 1859.

This consists in fitting a corn and seed drill on the beam of a plough behind the turnfurrow, and in obtaining motion in the seed hopper by a wheel travelling on the sole or bottom of the furrow; a set of cog-wheels which turn a shaft passing through the seed hopper is set in motion by the wheel travelling in the furrow. A sliding nut moved by a lever is attached to one of a set of cog-wheels to regulate the delivery of the grain. When not in use the drill is raised by a lever attached to a cross-piece on the handles of the plough. *Patent completed.*

694. J. W. DUNCAN and J. E. A. GWYNNE. "Improvements in, or connected with, apparatus for the generation, application, and condensation of steam, part of which apparatus or arrangements is applicable to other purposes." Dated March 18, 1859.

This invention has reference to a previous patent dated 9th Feb., 1856, and consists, 1, in arrangements for producing pure and perfect combustion of the gases, the clearance of ashes or soot, maintaining the surfaces in a good condition for utilizing the heat in producing steam and increasing the draught. 2. In insulating the steam pipe leading from the boiler to where the steam is to be used, by inclosing it inside a pipe of large diameter, which may contain felt, glass, air, or other substance, and over the second concentric pipe another of a still larger diameter is placed to convey the exhaust or waste steam between the inside of it and the outside of the second pipe; the return steam prevents radiation of the heat from the central pipe of the series which conducts the steam to the engine. The cylinders of the engine may be jacketed on the same system. *Patent completed.*

695. T. ALLEN. "Improvements in petticoats." Dated March 19, 1859.

This consists in making an air-tight petticoat of two thicknesses of suitable material, capable of being inflated by means of a mouth-piece. *Patent abandoned.*

696. W. B. GINGELL. "Improvements in the form of metal bars used for the stiles, rails, heads, and sills of window-sashes, casements, and other lights." Dated March 19, 1859.

The inventor forms longitudinal ribs, flanges, or projections on metal bars used for the stiles, rails, heads, or sills of window-sashes, casements, skylights, or other like framework or fittings. *Patent completed.*

697. E. L. BENZON. "An improvement in the casting of steel." (A communication.) Dated March 19, 1859.

This consists in heating the mould prior to pouring in the steel. For hard and soft steels different degrees of heat will be required. *Patent abandoned.*

698. S. STERN. "Manufacturing a resinous carton or pasteboard from vegetable matter, an improvement for roofing, ship sheathing, lining walls to prevent dampness, and other uses." (A communication.) Dated March 19, 1859.

Here the vegetable substance is dried in a stove, passed two or three times through the grinding mill, and plunged into a hot solution of the resinous mixture; it remains in this solution for several minutes, is then withdrawn and hung to drip in a small close stove. After the carton has been thoroughly dripped it is placed in a vaulted stove, where it remains until the volatile oils arising from the resinous mixture have been evaporated. The carton is next removed from the stove and placed between two plates, and passed between two rollers to give it a finish. It is next exposed to the atmosphere until ready for use. *Patent abandoned.*

699. H. WHITAKER. "A new musical instrument to be called 'The Cherubine Minor.'" Dated March 19, 1859.

This consists in combining the harp, the organ, and the glass bells into one harmonious piano. *Patent abandoned.*

700. J. W. HART. "An apparatus for the destruction of flies and other insects." (A communication.) Dated March 19, 1859.

Here the inventor places in a vase vinegar, ale, or other matter which will intoxicate or suffocate the insects. On the rim of the vases he places a ring having a ledge on which is distended a piece of paper with one or more holes of about $\frac{1}{4}$ th of an inch in

diameter. Around the hole or holes on the under surface of the paper he paints honey to induce the flies or other insects to pass through the hole or holes into the interior of the vase, where in a short time they will become intoxicated or suffocated and fall into the liquor. *Patent completed.*

701. W. HAIGH. "An improved manufacture of paper, to be employed for the purpose of packing, and other similar uses." Dated March 19, 1859.

This consists in the addition of a layer or layers of textile fabric, or fibre, between two or more thicknesses of paper, securing such fabric or fibre in its position by paste, and passing the whole between pressure rollers. *Patent abandoned.*

702. J. HOWDEX and A. MORROW. "Improvements in apparatus for obtaining and regulating motive power." Dated March 19, 1859.

The specification of this invention sets forth many improvements in connection with steam-engines and boilers, but is too elaborate for us to quote it here at sufficient length for an intelligible abstract. *Patent completed.*

703. R. MURPHY. "An improvement or improvements in the manufacture of cast steel." Dated March 19, 1859.

The essence of this invention consists in alloying cast steel with titanium in order thereby to improve the quality of the cast-steel, such cast-steel being prepared by melting blister or other steel in the manner ordinarily practised by manufacturers of cast-steel, and alloying titanium therewith during the process of melting. *Patent completed.*

704. W. and S. PICKFORS. "An improvement in stiffening, sizing, filling, or weighting textile fabrics." Dated March 19, 1859.

This consists in the application of a peculiar clay or shale found in Lancashire and other coal fields, generally covering the seams of coal, in substitution of, or in combination with flour or other matters, or substances, now used for like purposes. *Patent completed.*

705. A. V. NEWTON. "Improvements in propelling vessels." (A communication.) Dated March 19, 1859.

The patentee claims the use of reciprocating pushers working in open cylinders and with the propelling surface of the said pushers acting directly against the water beyond the ends of the cylinders, also the use of a reversed set of such pushers for backing the vessel. *Patent completed.*

706. W. C. CAMBRIDGE. "An improved construction of chain harrow." Dated March 19, 1859.

The object here is to construct chain harrows so as to admit of their being readily adapted by the attendant to heavy or light work. To this end the inventor forms the chain harrows of detachable parts or sections, so that a greater or less amount of harrowing surface may be attached to the whipple tree as described. *Patent completed.*

707. W. HAGGETT. "An improved method of treating metals and other materials to increase their strength." Dated March 21, 1859.

This consists in giving to iron and other metals by rolling, pressing, or casting, an undulated surface composed of longitudinal and transverse corrugations, crossing each other at right angles, diagonally or otherwise. The same principle is also applicable to wood, papier mâché, and all other materials capable of being pressed and moulded. *Patent completed.*

708. A. BAUCQ. "Maintaining graters mechanically." Dated March 21, 1859.

The inventor proposes in the manufacture of sugar to feed or maintain the graters by placing a mechanical apparatus or moveable bottom in the feeding trough, furnished with several knives to bring together the matters to be worked in, the grater to reduce such matters to the proper size, and to distribute them in the required manner. *Patent abandoned.*

709. W. HUDSON and C. CATLOW. "Certain improvements in looms for weaving." Dated March 21, 1859.

This relates to a previous invention patented 3rd July, 1857, No. 2025, and consists, 1, in dividing the comb into several sections or short parts, which are suspended from the axis of a bar occupying the place of the stock or back rib of the comb in the original arrangement, so that the motion of each section is independent of that of the others, but each of them when pressed towards the reed beyond a certain point acts upon the bar before mentioned so as to cause it to turn upon the axis through a small angle. Any one of the sections encountering the contemplated obstruction in the sheet is thereby caused to approach the reed, pressing against and slightly oscillating the bar. The latter carries the finger which strikes the stop piece, and which finger being slightly elevated by the motion of the bar stops the loom by the same means as in the original arrangement. 2. In discon-

necting the finger or arm which acts upon the web stopping apparatus from the comb so that the motions of the latter may not necessarily disturb the position of the said finger. The disconnected comb when its dents are urged beyond a certain limit, acts upon and raises the aforesaid finger into position for acting upon the web fork. The comb has imparted to it a separate and distinct motion proper to itself, and is turned and regulated so as to cause the dents of the comb alternately to enter into and withdraw from the warp, inserting themselves as the sley recedes, and disengaging themselves as it advances. *Patent completed.*

710. R. WHITTAKER. "Improvements in the manufacture or construction of metallic rollers or cylinders and mandrills for printing." Dated March 21, 1859.

This relates chiefly to such rollers or cylinders as are used by calico printers for printing and ornamenting textile fabrics, and it consists in so arranging and making the rollers or cylinders as to be capable of steadily withstanding the severe lateral strain of the printing action, whilst a small quantity of copper is used in them, and they are extremely manageable and easily charged and adjusted when in use. *Patent abandoned.*

711. G. FERGUSON. "The combination and application of certain materials for the destruction of insects and vermin." Dated March 21, 1859.

The inventor uses for the purposes of the invention creosote and oil of thyme, mixed in the proportion of four parts of the former to one of the latter. *Patent abandoned.*

712. J. ROBERTS. "Improvements in packings for pistons." Dated March 21, 1859.

The patentee makes use of a ring made of any suitable metal, and keeps it fully extended to the interior surface of the cylinder by screwed studs and nuts. *Patent completed.*

713. S. LEONI. "Improvements in the manufacture of useful and ornamental articles, surfaces, and works, parts of articles and parts of machinery or apparatus, from talc and other silicates of magnesia, and from the same combined with other substances." Dated March 21, 1859.

Here, the talc, steatite, &c., is reduced to a powder, and either alone or with glass, felspar, lime, or alumina, is pressed in a plastic state into moulds, and after being removed from the moulds is baked or burnt to the requisite hardness. *Patent completed.*

714. J. BICKERSON. "Improvements in opening and securing window-sashes." Dated March 21, 1859.

This relates to windows having sliding sashes, and consists in so fixing shooting or sliding bolts that a connection is secured by such bolts between the sliding edge or slide of the sash and a fixed part of the window frame. *Patent completed.*

715. G. GREGG. "Improvements in currying or manufacturing leather." Dated March 21, 1859.

The patentee takes the leather in its dry state and stuffs it with or applies to it oil or tallow. To prepare the leather for skiving, shaving, or splitting, he submits it to the action of water after stuffing, and he skives, splits, shaves, or flats the leather after the stuffing, oiling, or greasing operation. To extract the bloom he applies to the grain oil, tallow, or grease, and uses a brush, stone, pumice-stone, or other suitable tools, then glosses on the flesh, dries, grains up, and waxes. *Patent completed.*

716. W. WARNE, J. A. FARNSHAW, J. A. JACQUES, and T. GALPIN. "An improved compound or preparation of materials for, and mode of covering and insulating wires or conductors used for telegraphic or electrical purposes." Dated March 21, 1859.

This compound is composed of caoutchouc or gutta-percha, or the two combined, in combination with bituminous substances, to which may be added animal or vegetable oils and earthy matters, such as silicate of magnesia, rotten stone, &c. The wires to be insulated are passed through a vessel containing the compound, and through suitable dies. The insulated conductor is enclosed in a cover of woven fabric. This outer covering is payed over with some adhesive substance, on which is dusted a coating of pulverised glass or flint. *Patent abandoned.*

717. W. RHODES. "Certain improvements in fire-proof safes." Dated March 21, 1859.

This consists in adapting a supply of cold water between the inner and outer cases of safes. The water is admitted by a valve which is only acted upon by extreme heat, and this valve allows the water to flow into the aforesaid chambers or cavities prepared for its reception. In cases of fire as the water becomes heated it passes off, and cold water supplies its place. *Patent completed.*

718. G. P. A. LUTZ. "An improvement in veils." Dated March 22, 1859.

This consists in manufacturing veils of a circular, elliptical, or any other form in which the external edge is a continuous curve. *Patent abandoned.*

719. J. DAVIS. "Improvements in musical instruments." Dated March 22, 1859.

This relates to various modes of giving a direct rotary or partly rotary motion to the piston valves of cornets and other wind instruments. It also comprises other features, but the invention is not clearly described apart from the drawings. *Patent completed.*

720. P. TAGLIACCOZZO. "An improvement in metallic pens." Dated March 22, 1859.

The inventor manufactures writing and marking pens with the metal called aluminium, and with the alloys of this metal and copper, gold, silver, platinum, and any other metallic substances. *Patent abandoned.*

721. W. A. GILBEE. "An improved apparatus for stretching and polishing silk thread." (A communication.) Dated March 22, 1859.

This consists in the construction of an apparatus in which are employed a number of pegs or bobbins on which the skeins of silk to be operated upon are placed and receive a combined rotation and alternate circular or twisting motion and a regular and continuous tension. The invention is not described apart from the drawings. *Patent completed.*

722. W. WELLD. "Improvements in machinery and arrangements for coating slips, sheets, rods, and bars of metal, and laths, rods, and boards of wood, and similar articles formed of other substances, with paints, varnishes, and other like preparations, and drying the same." Dated March 22, 1859.

This consists in combining troughs, rollers, doctors, and brushes (rotating or stationary) for the purposes indicated in the title. *Patent completed.*

723. F. ASHFORD. "Improved means of fastening and securing treasure or bullion cases." Dated March 22, 1859.

This consists in passing bands of iron entirely round such cases or boxes, and bringing their ends together and uniting them by means of solder, such bands being further secured to the wood by nails. *Patent abandoned.*

724. J. T. PITMAN. "Improvements in springs for railroad cars and for other purposes." (A communication.) Dated March 22, 1859.

This invention is not described apart from the drawings. *Patent completed.*

725. E. MAYNARD. "Improving breech-loading fire-arms." Dated March 22, 1859.

This invention is not described apart from the drawings. *Patent completed.*

726. C. NEWINGTON. "Improvements in apparatus for distributing seeds and manure." Dated March 22, 1859.

To distribute seeds or manure broadcast a stopper is used having one side or part of a side hinged or moveable, so that the lower edge of the moveable side or part of a side, can be moved inwards and then back over the lower part of the hopper. The lower edge of such moveable side or part of a side is caused to move by blades or projections on a revolving axis below, and such blades in addition to giving a vibratory motion to the moveable part of the hopper, also cause the seeds or manure to descend on to a surface or platform below, to which a vibratory motion is also communicated. The seeds or manure will thus be caused to be shaken off from such surface or platform. *Patent completed.*

727. D. L. BANKS. "Improvements in suspension rail or roadways, and in machinery or apparatus connected therewith." Dated March 22, 1859.

This invention is not effectively described apart from the drawings. *Patent completed.*

728. W. P. WILKINS. "Improvements in the arrangements of valves, and in their application to steam-engines." Dated March 22, 1859.

This invention relates to circular valves which have rotary motion on their axes, and consists of various improvements in connection therewith, which we cannot here allude to in detail. *Patent completed.*

729. Sir P. FAIRBAIRN, and B. NEWTON. "Straightening and separating the fibres of silk waste, and laying them in parallel lengths preparatory to combing or dressing." Dated March 22, 1859.

The patentees interpose between the feed apron and the opening cylinder an arrangement of screw gills with feed and delivery rollers, which being driven at regulated speeds, superior to the surface speed of the feed apron, and inferior to that of the opening cylinder, will give the silk a preparatory straightening while conducting it to the comb teeth. *Patent completed.*

730. T. MANLOVE and W. HODGKINSON. "A

new method of manufacturing plain, figured, striped, and plaited textile fabrics in loom-made fabrics." Dated March 22, 1859.

This consists in manufacturing plain, figured, striped, and plaited textile fabrics by the aid of ordinary twist lace machinery, but with the addition thereto of certain mechanism, the object being to produce fabrics which resemble those now manufactured in looms. *Patent abandoned.*

ERRATA.

Abstract of specification No. 665 in our last number should have been marked as "*completed*" instead of "*abandoned*."

Reference to a wrong specification was made in No. 37, page 174. The abstract of specification No. 289 should have run as follows:—"This invention refers, 1, to an improved method of constructing the feeding parts, whereby the length of stitch can be regulated with the greatest readiness, and the feed be given with certainty. 2. To an improved method of forming the stitch itself, whereby the loop is drawn with certainty into the path of the looper or shuttle, the improvements being alike applicable to a double or a single thread machine. 3. To the application of a needle stripper and a cloth holder combined in one instrument, and made to operate in connection with the feed-foot and needle, in such manner as to be made to rest upon the cloth with different degrees of pressure at different times, so that whilst the feeding foot is lifted off the cloth to take a new feed, and the needle is being withdrawn, the pressure shall be greatest, and shall be least at the moment of the feed being given. *Patent completed.*"

PROVISIONAL PROTECTIONS.

Dated Aug. 6, 1859.

1813. A. S. Stocker and G. J. Farmer. Certain improvements appertaining to articles to be affixed to boots and shoes, and to the feet of animals, and in machinery and means to be employed for producing the same.

Dated Aug. 9, 1859.

1842. F. L. Lawrence. Improvements in colouring and hardening elastic gums for dental purposes.

Dated Sept. 12, 1859.

2074. H. W. Ripley. Improvements in finishing dyed piece goods.

Dated Sept. 14, 1859.

2090. S. Hecht. A new mode of advertising.

Dated Sept. 17, 1859.

2122. T. Elliott. Improvements in lubricators, especially applicable to steam engines.

Dated Sept. 20, 1859.

2137. A. Manbré. The manufacture of a coloring matter for coloring spirits, beers, vinegar, and other liquids and beverages.

Dated Sept. 21, 1859.

2148. H. A. Jowett. Improvements in breaks for railway and other carriages, with means of communication between guard or conductor and driver.

2149. J. Blair. Certain improvements in the treatment of yarns during the operation of spinning, which treatment is also applicable in "roving," "slubbing," or "doubling" machines.

2152. R. Davison. Improvements in the construction of holders for containing liquid or air and other aeriform fluids, especially adapted for use in refrigerators.

2153. J. Harrison. An improvement in spinning mules, applicable also to the machines called twiners.

Dated Sept. 22, 1859.

2156. R. B. Mowbray and T. Coatman. Improvements in machinery or apparatus connected with and applicable to steam boilers and heating apparatus.

2158. E. Jones. An improvement or improvements in the manufacture of coke in open coke fires or heaps.

Dated Sept. 23, 1859.

2160. C. J. Parry. Improvements in certain apparatus applicable to sewing machines.

2162. T. Bentley. Improvements in agricultural implements for gathering and destroying weeds and stubble.

2164. E. James. Improvements in machinery or apparatus for covering crinoline, applicable also to braiding fancy patterns for other articles.

Dated Sept. 24, 1859.

2166. J. Gedge. An improved stamp holder and cutter. (A communication.)

2168. J. Coey. Improvements in or applicable to packages for containing butter, lard, and other articles.

2170. T. B. Daft. Improvements in coating metal conductors, suitable for electric telegraphs.

2172. J. Todd. Improvements applicable to screw propellers in the propulsion of vessels.

Dated Sept. 26, 1859.

2174. J. Fernihough. Improvements in pistons, plungers, and buckets.

Dated Sept. 27, 1859.

2182. R. Coales. An improved preparation or preparations for promoting the growth and otherwise improving the hair, and for the application of a certain material for like purposes.

2184. C. Cowper. Improvements in mixing or combining and deodorizing oil made from gas tar and other oils. (A communication.)

2186. J. R. Piednue. An improved apparatus for transmitting motive power. (A communication.)

2188. P. J. Lejeune-Chaumont. Improvements in fire-arms and ordnance, and in projectiles and cartridges to be used therewith.

Dated Sept. 28, 1859.

2190. W. Collins. Improvements in stand pipes for hydrants.

2192. W. J. Dornier. Certain improvements in traction engines.

2194. E. S. Cathels and S. Splatt. Improvements in gas meters.

2200. P. Robertson. Improvements in the manufacture of manure.

Dated Sept. 29, 1859.

2202. C. Stevens. An improved steam dredging boat. (A communication.)

2203. G. G. Page and C. Lungley. Improvements in gangways or step ladders, applicable to floating bodies and other useful purposes.

2205. W. Johnson. An improvement in purses.

2206. E. H. Bental. Improvements in screw presses.

2207. C. Duplomb. Improvements in presses for pressing or finishing textile fabrics.

2208. A. W. Williamson and L. Perkins. Improvements in steam boilers.

2209. W. Kempe. Improvements in machinery for raising the pile of woollen and other cloths.

2210. R. Oxland. Improvements in the treatment of saccharine matters.

Dated Sept. 30, 1859.

2211. J. Wadsworth. Improvements in instruments or apparatus for measuring the quantity, for regulating the pressure, and for controlling the flow or passage of gas used for purposes of illumination, and in the construction of gas burners.

2212. T. Guibal. Modifying the installation and working of cables used in springing up mines.

2213. W. Hartley. Certain improvements in steam-engines.

2215. T. Buckham. Improvements in the switches for railways.

2216. J. O. Smith. Improvements in the construction of children's carriages called perambulators.

2217. B. Atkinson. Improvements in railway brakes.

2218. W. H. Buckland. Improvements in the preparation of pest.

2219. H. W. Hart. Improvements in argand and other gas burners, partly applicable to oil and other lamps.

2220. W. Clark. Improvements in railway signal apparatus. (A communication.)

2221. J. H. Johnson. Improvements in the construction of apparatus for reworking the waste steam of steam-engines. (A communication.)

2222. M. and A. Samuelson. Improvements in planing, slotting, and grooving machines.

2223. Hon. W. E. Cochrane. Improvements in chairs, and apparatus for receiving and securing the ends of the rails of railways.

2224. W. V. Edwards. Improvements in the construction of ways and apparatus to facilitate the conveyance of mails, goods, and passengers.

Dated Oct. 1, 1859.

2226. W. Parkin and J. Bates. Improvements in wedges for railway chairs.

2229. R. A. Broosman. Improvements in retre-

beratory, puddling, and other furnaces employed in the manufacture of iron. (A communication.)

2231. J. Millar. Improvements in reflectors for diffusing artificial light.

2232. L. Newton and J. Greaves. Improvements in cop tubes or spools, and in machinery for manufacturing the same.

2233. G. Bridgett. A new mode or method of manufacturing Shetland or other falls, from the stocking frame.

2234. J. Wright. Improvements in apparatus for raising water and minerals from mines, which improvements are applicable to raising and hauling weights generally.

Dated Oct. 8, 1859.

2235. E. Morewood. Improvements in coating metals.

2237. L. H. I. Lemaire. Improvements in the manufacture of chenille.

2238. W. R. Earle and E. J. Barnes. Improvements in photographic and other portraits.

Dated Oct. 4, 1859.

2239. G. F. Greiner. Improvements in the construction of pianofortes.

2240. M. A. F. Menmons. An improved coupling joint for pipes or tubes of soft metal, caoutchouc, gutta-percha, or other yielding matter. (A communication.)

2241. M. A. F. Menmons. An improved "porte-jupe," or apparatus for suspending dress-skirts and other objects. (A communication.)

2242. J. Loftus. Improvements in machinery for combing and carding cotton or silk and wool.

2243. R. and W. Hollis. Improvements in the construction of apparatus for winnowing and dressing grain.

2244. S. R. English. A machine or apparatus for taking copies of writing.

2245. B. Brearley, jun. Improvements in means or apparatus for raising the nap or pile of cloths.

2246. W. Backett. Improved cleansing powders.

2247. W. E. Newton. Improved apparatus for generating steam. (A communication.)

2248. J. M. Rose, R. Carle, and W. Pikesley. Improvements in drains.

Dated Oct. 5, 1859.

2251. J. Thompson and J. Thompson, jun. The manufacture of salt by an improved and more economical mode.

2253. A. Whytock. A mode or method of applying jointed sheets of metal for roofing and other purposes.

2255. J. Shields. Improvements in Jacquard looms or machinery for weaving.

2257. J. J. Eagleton. An improvement or improvements in annealing furnaces.

2259. G. Davies. Improvements in the method of, and apparatus for, vaporizing liquids and heating air. (A communication.)

2261. J. Scott. Improvements in the manufacture of anchors.

2263. W. E. Newton. Improvements in revolving fire-arms. (A communication.)

2265. W. L. Earle. Improvements in apparatus for promoting the combustion of smoke and gases arising from fuel.

2267. J. Macintosh. Improvements in the manufacture of flexible tubes.

2269. J. Macintosh. Improvements in coating metallic conductors for electric telegraphs.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Oct. 18, 1859.)

1369. J. H. Johnson. Reducing substances to powder. (A communication.)

1383. J. Ferrabee. Forming bats of sheet silver.

1386. K. H. Cornish. Bedsteads, sofas, &c.

1408. G. J. Farmer and G. B. Hardy. Stair rods and eyes.

1416. F. Palling. Lamps.

1417. T. F. Henley. Obtaining alcohol.

1421. G. C. Ash. Artificial teeth.

1422. B. Baugh. Raising metals.

1425. A. Smith. Purifying bees' wax.

1432. J. Dixon. Puddling steel.

1435. A. MacDonald. Punching patterns.

1441. E. T. Hughes. Lamp clock. (A communication.)

1440. N. C. Scerolmay. Preventing rust in metal.

1447. C. H. Waring. Safety lamps.

1458. H. Evette. Bedding.

1466. J. Combe and R. Smalpage. Spinning.

1479. J. Cox and S. and M. Frankham. Spurs.

1495. W. C. Fuller. Shackles and springs.

1510. A. J. Dessales. Sliding tubes.

1518. A. Chesneau. Paddle wheels.

1527. T. Leigh and J. Line. Paper.

1548. I. Tirebuck. Printing from plates.

1555. R. Kay, J. Manock, J. Whittaker, and T. Booth. Spinning, &c.

1621. W. Waite. Bonnets and hats.

1690. F. C. Bakewell. Extracting oils. (A communication.)

1756. P. Robertson. Ale and spirits.

1842. F. L. Lawrence. Gums for dental purposes.

1870. J. H. Johnson. Steam generators. (A communication.)

2022. F. C. Bakewell. Caustic alkalies. (A communication.)

2034. A. V. Newton. Flexible pipes. (A communication.)

2086. E. A. F. Lebourgeois. Surface printing.

2104. J. P. Clarke. Spools or reels.

2126. J. and C. Hawkins. Fly presses.

2157. J. Dales. Purifying sewage and water.

2201. D. Stewart. Presses.

2211. J. Wadsworth. Gas burners.

2215. T. Buckham. Switches for railways.

2221. J. H. Johnson. Steam-engines. (A communication.)

2233. G. Bridgett. Shetland falls.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the Gazette in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Oct. 13, 1859.

936. T. Bird.

938. J. Beattie.

943. A. McDougall.

945. S. Barnwell and A. Rollason.

949. G. Ashcroft.

951. J. Glasgow and S. Hand.

959. J. Hamilton.

959. A. Courage.

971. J. Whitaker.

972. J. Seaman.

977. J. Freer.

981. F. and W. Edwards.

985. P. and J. Reynolds.

992. Q. Beck.

995. A. W. Williamson.

1008. E. Clark.

1014. C. Mansel.

1019. W. Dicks and W. Hopwell.

1024. R. A. Brooman.

1031. G. Ward.

1035. J. Holmes.

1036. A. W. Gadesden

1037. E. Humphrys.

1062. Sir T. T. Grant.

1065. C. Randolph and J. Elder.

1070. E. A. Porteus and W. H. Burke.

1100. D. Moore.

1120. W. Clark.

1161. G. G. Bussey.

1183. M. Henry.

1197. W. Clark.

1222. L. D. Owen.

1251. W. C. Cambridge.

1500. G. T. Bousfield.

1554. T. Wright.

1698. J. Morgan.

1718. J. Hartley.

1706. J. Wood.

1774. W. Campbell and G. Worstenholm.

1803. R. T. Pattison.

1909. H. W. Harman.

1944. M. J. Stark.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

2395. A. B. Seithen.

2394. W. and J. Todd.

2403. R. A. Brooman.

2405. T. Allen.

2410. E. Tombs.

2423. G. Wilson.

2432. G. Morton.

2434. A. V. Newton.

2490. A. Lorimer.

2497. G. Blair.

2494. L. A. Dosachy.

2544. C. de Jongh.

2545. P. Fairbairn and R. Newton.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

350. J. Robinson.

358. H. H. Smith.

371. W. McFarlane.

399. J. Hopkinson, jun.

400. E. Leigh.

423. G. R. Tovell and J. Mann, jun.

492. E. Heywood.

557. R. Mallet.

781. S. Holt.

LIST OF SPECIFICATIONS, &c., Published during the week ending Oct. 14, 1859.

NOTE.—Specifications will be forwarded by post from the

Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

RAILWAY WORKS, Scotland.—For the erection on the Lymington, Bigger, and Broughton Railway, of several station-houses and cottages, goods-shed, engine-shed, loading banks, &c. Plans and specifications and detailed schedules at office of D. Thompson, Esq., Secretary, Bigger, or Messrs. Bruce and Cunningham, engineers, 21 Castle-street, Edinburgh. Tenders to Secretary, Oct. 31.

RAILWAY STATION, Lancashire and Yorkshire.—For enlargement of passenger station, Rochdale. Plans, &c., Engineer's office, Hunt's Bank, Manchester. Also for the construction of stables at Oldham-road station. Particulars as above. Tenders, to Directors, and sent to Secretary, Mr. W. S. Lawn, Nov. 1.

RAILWAY CARRIAGES, Stockton and Darlington Railway.—For two or four first, eight second, two third class, and six composite carriages; with four vans. Plans and specifications, with pattern carriages, at the Railway Company's Coach Works, Darlington. Tenders, Railway Office, Darlington, 3rd Nov.

MINERAL WAGGONS, North Staffordshire Railway.—The Directors desire to hire for a period not exceeding five years, 250 low-sided mineral wagons, to carry five tons each. The tenders to Mr. S. Samunda, the Secretary, Stoke-upon-Trent, Nov. 8. A sample wagon to be provided for the inspection of the directors.

SLEEPERS, Lymington, Bigger, and Broughton Railway.—For the supply of several thousand large sleepers of various sizes. Further particulars, Messrs. Bruce and Cunningham, Engineers, 21 Castle-street, Edinburgh.

RAILWAY STORES, Midland.—For stores for one year, from January 1st to December 31st, 1859:—1. Coal—locomotive, house, furnace, and gas; 2. Iron—lines, axles, sheets, &c.; 3. Copper, brass and tin—sawyer ingots, rods, sheets, pipes, &c.; 4. Steel, &c.—cast, shear, blisks, and spring; 5. Axes, saw blades, &c.; 6. Wheels—wrought-iron centres for engines, tenders, carriages, and wagons; 7. Ironwork—bolts, nuts, washers, nails, tanks, screws, &c.; 8. Iron Castings—for locomotive, carriage, and other purposes; 9. Axles, bolts, &c.; 10. Ironmongery—locks, hinges, fenders, &c.; 11. Fittings—engine, syphons, cocks, union joints, &c.; 12. Timber—oak, elm, ash, mahogany, pine, deals, &c.; 13. Chair Keys for Permanent Way. Patterns at General Stores Department, Derby, 26th inst.; two forms of tender on same date from Mr. Pettifor, Derby. Tenders, addressed to General Stores Committee, Derby, by 10 a.m., Nov. 14.

BRICK SEWER AND IRON PIPE, London.—For construction and laying down of brick sewer and iron pipe the length of 508 feet, with other works in connection therewith, in the Park-road, Regent's Park, Middlesex. Plans, sections, and a specification, with a form of tender, may be inspected, and particulars obtained at office of Metropolitan Board of Works, 1 Creek-street, Soho, to the 27th inst., where tenders by 4 o'clock.

STREET LIGHTING, Westminster District.—For lighting with gas, oil, paraffine, or otherwise, the public lamps in the several streets, squares, and other public places within and under the jurisdiction of the Board of Works for Westminster district (except that portion called the hamlet), for a term of one, two, or three years, from the 25th of December next. Particulars at the offices of the Board, Great Smith-street, Westminster. Tenders, Nov. 4.

TOWN HALL, Halifax.—For the bricklayers' and masons', carpenters' and joiners', smiths' and founders', slaters', plasterers', and the plumbers', painters', and glaziers' works, for the erection and completion of new town-hall, Halifax, from the designs of Sir C. Barry. Drawings, &c., Council Chamber of Town-Hall. Blank bills of quantities may be obtained at the telegraph room of the Mechanics' Hall upon the payment of 10s. Tenders, Oct. 25th.

CHAPEL, Grimsby.—Plans, &c., in the vestry of George-street Wesleyan Chapel. Further information of Messrs. Bellamy and Hardy, of Lincoln, or Rev. T. Hughes, and Mr. J. Burnet, Secretaries, Grimsby, Tenders, Oct. 29.

ALMS-HOUSES, Grindleton, near Clitheroe.—Plans, &c., Mr. T. Barker, the Duke of York Inn, Grindleton. Further information at Messrs. Mallinson and Healey, Tyndal-street, Bradford. Tenders, Oct. 24.

ARMY MEDICAL LECTURE THEATRE, &c., at Fort Pitt, Chatham, Kent.—Parties tendering must leave their name at office of War Department, Chatham, Oct. 22nd, and pay 10s. 6d. for bills of quantities.

HOUSES, Erith, Kent.—Drawings, &c., Mr. C. F. Maltby, 73 Coleman-street, City, E.C.

PRACTICAL MECHANICAL ENGINEERS.—Accustomed to the use of the indicator, valve setting, &c. He will be required to travel occasionally, and must be capable of taking dimensions of work. Address, with references, stating age, experience, and salary required, Box 90, Post-office, Ashton-under-Lyne.

WORKING ENGINEERS.—For the Essex Lunatic Asylum, Hayward's Heath. Wages 3s. a-week, with the use of the lodge, gas and water. Testimonials to Dr. Robertson, at 1 Asylum, Oct. 28.

FIFTY COLLIERIES.—Fifty Thin Seam Colliers wanted immediately for the West Wilts Collieries, near Barnsley. Constant employment, from 4s. 6d. to 6s. per day. Apply to Mr. B. W. Moody, on the Works.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 28, 1859.

THE COST OF GOVERNMENT AND
MERCHANT SHIPBUILDING.

WE are often hearing much, in the House of Commons and elsewhere, about the extravagancies of the ship-building departments of our dockyards. Not very long since Mr. William Schaw Lindsay had the audacity to state in his place in Parliament that shipwrights' labour which cost £8 13s. 11d. per ton in Her Majesty's Dockyards cost but £2 12s. in private establishments, and that out of £1,000,000 voted for shipwrights' work £400,000 might be saved, and "the work would not be one whit less efficiently done." We have already shown* that these statements are monstrously false, and we might well leave them, if they stood alone, without further comment; but having before us the Report of the Committee of Economy, which formed the ostensible basis of these observations, a further consideration of the subject seems desirable.

In so far as Mr. Lindsay himself is concerned but little need be said. We believe him to be one of the worst enemies to true reform that ever held a seat in the House of Commons. Reform is safe when its enemies avow their principles, and pursue a course of honourable, if erroneous, opposition to it; but when a man springs up with the cry of reform upon his tongue, and glibly puts forth statements which have not the slightest foundation in fact, and which every man of sense and intelligence must see to be false, who shall say how much harm the cause of improvement suffers? And this is what Mr. Lindsay has been doing ever since he continued to force himself into prominence as member for Tynemouth. We all remember his flagrant speeches of 1855, made ostensibly in the interests of Administrative Reform, but which did more injury to the Association that had control of that movement than the bitterness of its opponents were able to inflict upon it. If the nature of these speeches should have been lost sight of by any of our readers the memory of them may be revived by reference to Sir Charles Wood's reply, published in the newspapers of June 23, 1855—a reply which should have silenced Mr. Lindsay for ever. But we need not go back so far to learn Mr. Lindsay's character. We have seen enough of him lately in our own columns to satisfy us. Mr. Lindsay sat, be it remembered, as a liberal member for Tynemouth, and now sits in the same capacity for Sunderland. How came it to pass, then, that he put himself under obligations to a Tory Government? That he did so we know, for his own man, Bowman, has told us so—told us that Mr. Lindsay got him put upon the Admiralty Committee. How came Mr. Lindsay to be on such good terms with a Tory Admiralty? Let every man of common sense and sagacity answer the question for himself. If he needs help in answering it he may remember that when the crisis of Lord Derby's Government came, Mr. Lindsay voted *against* the Liberal party. He nearly lost his seat by his vote; had the Sunderland electors known all, he would have quite lost it!

But, to come to the shipbuilding question, we believe public opinion is very much at fault respecting it. We honestly think, nay, we know perfectly well, that the shipwrights of our Royal dockyards work quite as hard and as well for every shilling they earn as shipwrights in private dockyards. We have been familiarly observant

with both systems. We have closely watched shipbuilding operations in the private service oftentimes; we know our public dockyards well; we have conversed scores of times with officers who have supervised work in both; and we unhesitatingly say that the Government shipwrights are in no way inferior, either in skill or diligence, to others. This is saying the very least that is due to them. And, of course, the whole question of economy, in so far as the cost of work is concerned, is involved in this consideration. We say nothing here of collateral matters, nor can we receive, in contradiction to our statements, any evidence as to what dockyard accounts show. These do not affect the actual cost of "shipwrights' work." Our point here is, that the shipwrights of Her Majesty's dockyards earn their money as honourably and as unquestionably as any shipwrights in the kingdom; and we challenge Mr. Lindsay to prove, or even to give a colourable reason for saying, that they do not. Bad officers sometimes exert bad influences upon the men, and none are more likely to do this than over-active captain or admiral superintendents. When these naval gentlemen are given to meddling with what they do not and cannot understand, mulcting every man whom they happen to detect doing nothing, whether he be an industrious man or not—in other words, when dockyard superintendents convert themselves into a malignant sort of policemen, as they sometimes do—then mischief ensues. We remember many instances of this kind; we may mention one. A certain captain superintendent discovered two shipwrights who appeared to be chatting at the ship's side, and, although the men were really talking over a difficult piece of work which they had to do, and which required consideration, they were mulcted of a day's pay: the same officer at about the same time detecting a workman filing down a piece of *lignum vite* wood at a bench, was well satisfied to learn, at his own suggestion, that the man was "sharpening his mallet," although the fellow was in truth preparing material for a medicinal infusion! If this officer had been either just or wise, he would neither have fined two men undeservedly nor have made himself the laughing-stock of a third. As it was, he, like many others, injured the service by making every man feel that he must keep a careful eye upon him, which could only be done at the expense of the work itself. We might mention other causes which occasionally operate against the diligence of the Government workmen; but as these are exceptions to the rule, we need not dwell upon them.

It is not a little astonishing that such men as Mr. Murray and his colleagues should have ventured to pronounce judgments upon the shipbuilding operations of our dockyards. Mr. Murray would be the last man in the world to consider shipwright officers justified in discussing the details of his department, and a very small amount of modesty would have sufficed to warn him against entering, as he has done, upon a criticism of their business. Yet it was he and Mr. Bowman who originated the monstrous statements before quoted, which Mr. Lindsay reproduced with so much unction. We must quote the paragraph (967) in which they finally deliver themselves of their conclusion upon this question:—

"Eight of the corvettes before referred to, 'cost, for shipwrights' labour, without fitting for sea, 109s. 8½d. per ton, and one fitted for 'sea cost 173s. 11d.; while it was stated in 'evidence to the Committee, that a corvette, 'if built in a private yard, with scantlings, 'fastenings, and workmanship similar to ships 'in Her Majesty's navy, fitted for sea, would 'be about 52s. only per ton for shipwrights'

'labour. Allowing for any superiority in 'workmanship in the dockyard, or other difficulties, [*etc.*] the Committee can see no reason 'why ships should not be built for a price in 'the dockyard at least approaching to that 'paid in private trade, if the same system of 'working the men, as now recommended, be 'adopted, instead of their costing, as in the 'case above quoted, more than three times as 'much.'"

Can it be possible that this Committee was so utterly ignorant of what they wrote about as to believe that ships of war can be built and equipped for sea for 52s. per ton? Or, if they were so, can Mr. W. S. Lindsay, the great shipowner, the man who puts himself up as an authority on such questions—can he have known no better? It is only charitable to believe he did. Let us hear, however, what Mr. Pitcher, the shipbuilder of Northfleet, says upon the subject. When the remarks of the Committee began to find their way into the public press, he addressed to the Surveyor of the Navy the following letter:—

"Northfleet Dockyard, 11th July, 1859.

"SIR,—I cannot permit the statements which 'I have read in the *Times* of Saturday to pass 'unnoticed. It is there asserted that the labour 'for building a vessel of war in the merchant 'yards does not exceed the sum of £2 8s. per 'ton for shipwrights' labour; but it should be 'understood that the ships alluded to were 'mere shells when sent to Her Majesty's yard 'at Chatham, to be fitted as might be required, 'as the cost of such fittings would depend very 'much upon the service they were intended 'for. I am of opinion that the vessels built 'for the Government in private yards, when 'compared with those built in the Royal Dock- 'yards, according to the evidence published, 'amounts to very near the same sum for the 'total completion in the hull; for instance, in 'the labour for building about 13,500 tons of 'the gun-vessels at Northfleet, they cost, on an 'average, complete, about £6 per ton.

"Trusting that you will not consider me 'intrusive in offering these my observations, 'pray believe me, &c.,

(Signed) "HENRY S. PITCHER."

To this letter the Surveyor of the Navy appends the fact that from the examination of accounts recently made, it is found that the cost for shipwright labour in building and fitting for sea the corvette alluded to by the Committee (the Pearl) is not £8 13s. 11d. per ton, but £7 2s. Mr. Chatfield, in his counter report, throws much further light on this question. He tells us that returns as to the state of the two vessels alluded to by the Committee and Mr. Pitcher—the Cossack and Tartar—have been obtained from Chatham Dockyard, where these ships were completed in 1854-5, and the returns show that on the Cossack the sum of £3,597 was expended in completing the hull, £2,087 on materials, and £1,510 on workmanship, and nearly equal sums upon the Tartar. He further tells us that when the Cossack was repaired for a second commission in 1858 no less than £5,771 had to be expended upon her; many of her planks were found to have been broken in the working. As Mr. Chatfield remarks,—"the fact of the Cossack 'requiring £9,368 to be expended upon her 'within a period of four years, was certainly 'not a very remarkable instance of the economy 'of private shipbuilding beyond that of public 'departments.'"

It may be well, perhaps, before quitting this subject, to show that we are not alone in our estimate of the Government shipwrights and their work. Mr. William Brown, who spent several years in the private service, having

* See MECHANICS' MAGAZINE for July 22.

been a working shipwright at Messrs. Wigram and Greene's, and a foreman of Mr. Graham's at Harwich, in evidence before the Committee, said, "In the Government service the work is 'materially better; it is three times as well done, and worth three times as much money.'" He also said, "I think there is a better feeling 'among the dockyard men to get through a 'day's work (even on day-pay) than there is 'among the river men when they are working 'for a private master.'" Mr. William Baines, the present Timber Inspector of Deptford Dockyard, a very experienced officer, said, "I 'have seen all sorts of work and workmen, and 'I am fearless to assert, and capable at any 'time to prove, to any shipwright, that there is 'more, better, and harder work performed by 'the shipwrights in Her Majesty's Dockyards 'for the money paid than in any other part of 'the world, and the workmen, taken as a body, 'much superior to any private establishment I 'ever saw." We could readily multiply such testimony.

MR. FAIRBAIRN'S STEAM EXPERIMENTS.

MR. WILLIAM FAIRBAIRN, aided by his mathematical friend Mr. Thomas Tate, has once more been performing experiments which scientific men will gladly welcome. On another page of this number we print the results of some recent inquiries of theirs into the law which connects the varying densities and temperatures of steam.

It has long been suspected—or rather, it has long been placed beyond suspicion—that the law put forward by Dalton and Gay-Lussac, however sound as applied to ordinary gaseous bodies, is not correctly applicable to steam, or, indeed, to any condensable vapours whatever, although it has formed the basis of all our standard writings on the subject. Dr. Joule and Professor W. Thomson were first led, some time since, to notice the failure of the law in this respect, owing to discrepancies which they discovered in applying what is called the Dynamical Theory of Heat to Carnot's law, and later Professor Rankine has gone so far as to put forth a new formula favouring the view of Joule and Thomson, and opposing that of Dalton and Gay-Lussac. With the question in this condition Mr. Fairbairn has turned his attention to it, and very properly decided upon appealing to experiment for evidence of the truth of the matter.

The details of the experiments undertaken by Mr. Fairbairn and Mr. Tate are set forth with sufficient fulness in the paper above referred to. The results deserve especial mention. Expressing the density of the steam by means of numbers representing how many times the water composing it has been expanded, they obtain some very remarkable departures from the results given by the old formula. For example, where the latter gave 1005 for a temperature of 244°, the experiment gives 896 only; for a temperature of 245°, the formula gave 969, the experiment 890; for 257°, the numbers were 790 and 651; for 262°, 740 and 680; for 268°, 680 and 633; for 270°, 660 and 604; and for 283°, 540 and 490. These determinations at pressures varying from ten to fifty lbs. above the atmosphere are, as Mr. Fairbairn says, not accurate reductions from the experimental results, but only approximations. They uniformly show, however, a decided deviation from the law for perfect gases, and in the direction anticipated by Professor Thomson, the density being uniformly greater than that indicated by the formula. Mr. Fairbairn hopes by the time of the next meeting of the British Association, with the assistance of his friend Mr.

Tate, to be enabled to lay before the section a series of results which will fully determine the value of superheated steam, and its density and volume as compared with pressure at all pressures varying from that of the atmosphere to 500 lbs. on the square inch. The facts which he thus hopes to ascertain are very much needed, and we heartily tender him our thanks, on behalf of the scientific public, for his labours in the matter. The fact of many of our first engineers taking patents for every conceivable form of superheating apparatus is a very significant sign, and there are no doubt great advances to be made in that direction.

MR. RUSKIN ON THE WORKMAN AND HIS WORK.

MR. RUSKIN is a gentleman of very high culture, tastes, manners, thoughts, and pursuits, and as such deserves honour of individuals and of society. He is possessed of extraordinary energy, vivacity, keenness of sight and of analytic power, and lives a life of wonderful activity, as a thinker and writer, traveller and artist.

There are two kinds of writers in the world. One man writes as possessed by a power behind and beyond his own volition and reflection, producing and creating through him: the writers of this type are the warm, rich, genial nourishers and enrichers of the world. Another type of man is he who deals with the material that genius has produced, labours at it, manipulates it, analyses it, reflects on it, distinguishes and classifies its separate parts, interprets and applies it. Mr. Ruskin is eminently a writer of the latter kind. In all his writing he always impresses you as working hard, as conscious, reflective, and of narrowly-defined aim. The world has need of both types of man, and thankfully accepts them both with all their differences.

Goethe says that in our fourteenth year we generally paint black and white very close to each other, and fail to see the innumerable subtle gradations by which each melts into the other in nature and in life. Goethe might have said the fortieth year of too many of us. Mr. Ruskin's great failing is just this: he makes most exaggerated, one-sided distinctions and classifications: for example, when he says that the Greeks made the living human form their sole study, and proudly disdained nature in her lower and humbler shapes, we call to mind that the horse, ox, and ram are as exquisite as the human figures in the Greek sculpture, and that Homer had the quaintest fondness for nature's plainest and humblest forms. Mr. Ruskin has committed himself to the most narrow and dogmatic assertions in some of the highest branches of human inquiry. He often writes in a most dictatorial and schoolmasterish tone. Often he seems to us a ceaseless talker, and not at all because of that redundancy of words, which, like Shakespeare's or Goethe's, is the welling up and overflowing of an opulent, inspired soul. For all that, we confess we always read every fresh work of his, and always find him so vigorous, clear, varied, honest, and earnest, that we heartily thank him each time for his book.

The post Mr. Ruskin pre-eminently occupies as a writer, and which mainly concerns us in the pages of this journal, is that of communicator and interpreter between English thinkers and workers. His effort is to infuse our thinkers' thoughts into our workers and their work. What he teaches is not something new he has discovered, or anything new in itself, properly speaking. Our best things are our oldest. The sun-rise, the mother's love, the beauty and poetry of childhood, are not newest,

though they are of our best. The oldest facts, as experiences, visions, convictions in new and living men, are what we want. Mr. Ruskin's main idea is a very old one; it is this: that the work of man's hand reveals the worker; that whatever man works at, his supreme aim should be to pour as much of himself, as much of his intellect, taste, enthusiasm, affection, imagination into the work as the work is capable of receiving; that that is the highest work of man in which he can embody the greatest number, fulness, and intensity of human elements; and that he is the highest worker who can impress most clearly and completely the image of man upon his work. We cannot attempt to follow Mr. Ruskin in his endless applications of this principle, but must content ourselves with two or three examples. In his last volume, "The Two Paths,"* he tells the people of Bradford, that those who design the patterns for pottery, carpets, wall-papers, curtains, and apparel, should be reared and live amidst beautiful natural forms, and strive to repeat these. He complains, in this volume, that architecture is made a mere science of mathematical proportions in our day. The disposition of lines and masses in agreeable proportions—as in any work of Sir Christopher Wren's—he grants to be a task for genius alone, but only for a fractional part of human genius. He contends that in old Gothic architecture the walls and buttresses, the pointed arches, and steep gabled roof were but the mere outline and framework of those grand old edifices; and that the real work of those old builders was to cover and fill up that framework with endless reproductions of organic shapes from the floral, animal, and human worlds. So that all our talk about a new style of architecture is purely idle; and it matters little what outline and framework the architect adopts, but a great deal that he should be a student of God's creation, and should glorify his edifice with records of the visions and raptures God's world has afforded him. From the same point of view Mr. Ruskin pities the man who has no room in his work for the expression of himself. We quote from his "Stones of Venice":—

"We have much studied and much perfected, of late, the great civilised invention of the division of labour; only we give it a false name. It is not, truly speaking, the labour that is divided, but the man; divided into mere segments of man—broken into small fragments and crumbs of life; so that all the little pieces of intelligence that is left in a man is not enough to make a pin, or a nail, but exhausts itself in making the point of a pin, or the head of a nail. Now it is a good and desirable thing, truly, to make many pins in a day; but if we could only see with what crystal sand their points were polished—and of human soul, much to be magnified before it can be discerned for what it is,—we should think there might be some loss in it also. And the great cry that rises from all our manufacturing cities, louder than their furnace blast, is all in very deed for this—that we manufacture everything there except men; we blanch cotton, and strengthen steel, and refine sugar, and shape pottery; but to brighten, to strengthen, to refine, or to form a single living spirit, never enters into our estimate of advantages."

What a voice there is for our "industrial age" in the great principle we have been hinting at. What will deliver us from sham-work and half-work in our manufactures? What will lift our industries above the petty squabbles about price of labour? Awaken in men this old law, implanted in us all by our Maker, that whatever a man does he should do it with his whole heart, his whole self. Teach a man that his work is an emblem of himself; that a piece of work slovenly, stupidly, uglily, half done, shows a sloven, stupid, ugly,

* The Two Paths; being Lectures on Art, and its application to Decoration and Manufacture, delivered in 1858-9. By JOHN RUSKIN, M.A. London: Smith, Elder, and Co., 65 Cornhill.

half man; that such a piece of work is a gross immorality in the sight of nature and mankind; that it re-acts on the worker, and confirms him in the bad elements he has imprinted on his image; that if all men worked as he works, we should in one year reach general bankruptcy and rottenness. But teach him that if he brings attention, conscience, taste, enthusiasm to that work, that such work is a living, breathing embodiment of morality and religion; that whenever he looks at it, it will give him faith in himself, and encouragement and hope for himself; that wherever it goes it will give assurance of the existence of so much human worth and beauty, making men believe in human worth and disbelieve in human baseness.

If we had space we would faintly quote at large from Mr. Ruskin's noble pages about labour. Take the following from his "Stones of Venice," on the honourableness of manual labour:—

"We are always, in these days, endeavouring to separate intellect from manual labour; we want one man to be always thinking, and another to be always working, and we call one a gentleman and the other an operative; whereas the workman ought often to be thinking, and the thinker often to be working, and both should be gentlemen in the best sense. As it is, we make both ungentle, the one envying, the other despising his brother; and the mass of society is made up of morbid thinkers and miserable workers. Now, it is only by labour that thought can be made healthy, and only by thought that labour can be made happy, and the two cannot be separated with impunity. It would be well if all of us were good handicraftsmen in some kind, and the dishonour of manual labour done away with altogether."

Let the following extract from the close of the first lecture in "The Two Paths," conclude our hasty remarks:—

"All of you have the trial of yourselves in your own power. Each may undergo at this instant, before his own judgment-seat, the ordeal by fire. Ask yourselves what is the leading motive which actuates you while you are at work. I do not ask you what your leading motive is for working—that is a different thing; you may have families to support—parents to help—brides to win; you may have all these, or other such sacred and pre-eminent motives to press the morning's labour and prompt the twilight thought. But when you are fairly at the work, what is the motive then which tells upon every touch of it? If it is the love of that which your work represents—if, being a landscape painter, it is love of hills and trees that moves you—if, being a figure painter, it is love of human beauty and human soul that moves you—if, being a flower or animal painter, it is love, and wonder, and delight in petal and in limb that move you, then the Spirit is upon you, and the earth is yours, and the fulness thereof. But if, on the other hand, it is petty self-complacency in your own skill, trust in precepts and laws, hope for academic or popular approbation, or avarice of wealth—it is quite possible that by steady industry, or even by fortunate chance, you may win the applause, the position, the fortune, that you desire; but one touch of true art you will never lay on canvas, or on stone, as long as you live."

THE LIBRARY COMPANY.

A COMPANY under this title has been started at 22 Paternoster-row, for the purpose of supplying libraries of standard works to all classes. It is not our object here to make that portion of the design which has any other interest than that of the working man, or the middle classes, more popular, although the wealthy, we fear, in too many cases, need a little gentle stimulus to do more than to provide themselves with a good library—to read it. The address, which is before us, states that there never was a time when the activity of the press was so great as at present, and when the number of readers was so large, and so continually on the increase. But

when we inquire what the people read—whether old books or new, good books or bad—the answer is not so satisfactory to the moralist and the well-wisher of his kind as the mere statistics of the activity of the printing press might seem to warrant. There is a large class of people—they may be numbered by hundreds of thousands—who read little but religious tracts adapted to the intellectual capacity of children. There is another class, quite as large, who read little or nothing but the cheap periodical publications, containing the police-reports, and the records of murders and prize-fights. There is another class, perhaps quite as large as either, who read prurient or silly novels and stories, provided by cheap weekly periodicals, and to whom the best works of the greatest English authors are scarcely known, even by name. Those who look into the cottages or houses of the working man, and even of the clerk or the tradesman, seldom find any books but an old almanack or magazine, and still seldom a library, however small. Sometimes a few odd volumes are used as a base for the tea-caddy or the work-box; but beyond these nothing is to be found worthy of the name of literature. In the villa of the merchant, the drawing-room table, and a small ornamental book-case, often contain the elegantly-bound, but too often useless or exhausted literature of the family. In the houses of the professional and upper classes only are to be found books in such quantities as to deserve the name of a library.

To help the public to supply this deficiency, to aid the working man in selecting for himself something better than obsolete, silly, or pernicious novels, that pander to the lowest tastes and instincts; to give to the clerk and the tradesman a literature of substantial books, and to impress upon the merchant and the owner of the villa that a good library ought to be as essential to their position and their comfort as a good wine cellar, and that good books are even more necessary than good paintings; to enable large houses of business to establish suitable libraries for their clerks and young men, at a moderate cost; and generally to aid all classes of the community in the task of selecting such libraries as may be within the compass of their means, is announced as the object of the promoters of the Library Company.

"They are of opinion that the name of Dr. Charles Mackay offers a sufficient guarantee that the books will be well chosen from the masterpieces of English literature, and that, whether instructive or merely amusing, their elevation of tone and purity of character will be such as have received the sanction of public opinion and the award of the highest criticism. It will be made a principle of the company's operations that no books of sectarian or controversial theology shall be included in the list; but if a purchaser desire to make any alteration in this respect, he will be allowed to substitute such or any other books of the same price. Particular attention is called to the fact that the libraries are exchangeable at half the price charged, within twelve months of the purchase, if in good condition."

These libraries, it would appear, will be supplied at from £1 to £1,000. For instance, the Working Man's Library for £1 contains twenty-six volumes bound in thirteen, and includes the histories of England, Scotland, Ireland, and France; a Biographical Dictionary, Travels, and Voyages of Discoveries in Europe, Asia, Africa, and America, and other useful works indispensable to the working man. For an extra £1, Astronomy, Geology, Fiction,

Poetry, and miscellaneous works by well-known authors. For another £1 the selection rises still higher, and so on. The Cottage Library is likewise happily selected. The Boys' and Girls' Library, the Family Library, the School-room Library, the Institute or Family Library, the Fifty-Pound Library, &c., &c., follow in like order, and are equally well arranged for the several classes for whom they are designed.

The movement is a wholesome one, and highly characteristic of the period. We wish it every success, and are right heartily glad to hear that it is already receiving support from those practical and philanthropic minds which are ever the first to seize upon a useful object, and carry it effectively to the most beneficial consummation.

THE SOVEREIGN AND THE SHILLING.

ALTHOUGH the above-named coins are exceedingly popular, and are ever moving from hand to hand, and from pocket to pocket, yet how few persons know exactly their dimensions, weight, or the precise composition of the metals of which they are made! With the impressions upon them we are all happily familiar; but it is right, too, that their other characteristics should be known. As the more aristocratic coin of the two, statistics of the sovereign may be first given. The sovereign contains, when passing in the bloom of youth from the Mint, 113,001 grains of *fine* gold, but the addition of alloy-copper makes it weigh actually 123,274 grains of *standard* gold, or decimally 0.2568 oz. Its diameter is 0.863 in. The lb. troy of standard gold—which at the Bank of England is invariably £3 17s. 10½d. per oz.—is therefore coined into £46 14s. 6d. current money, or 46½ sovereigns. A million of these very interesting coins would weigh 10 tons 14 cwt. 0 qrs. 14 lbs. 2 oz., and if they were placed on the ground in single file and touching each other they would form a golden track fourteen miles in length. At the Mint it would take a week to spin such a thread.

Let us turn now to the more plebeian shilling. The new shilling contains 87½ grains of standard silver, and standard silver consists of a mixture of fine silver and copper, in the proportions of 11 oz. 2 dwts. of the former to 18 dwts. of the latter. Its diameter is 0.915 in. The lb. Troy is coined into sixty-six shillings. The value of a ton weight of shillings (current) is £6,600, and the cost of a ton of standard silver in the market averages £6,000. A million pounds worth of shillings (£1,000,000) will thus be found to weigh 151 tons 10 cwt. 1 qr. 5 lbs. 3 oz. 12 dwts. 17½ grs., whilst the number of pieces would, of course, be 20,000,000. It is supposed that there are in existence at this hour 50,000,000 of sovereigns and about 120,000,000 of shillings! enough, one would think, for the wants of Her Majesty's lieges, scattered though they be over the two hemispheres. But these quantities are ever being added to, and other countries are always supplementing them with their own peculiar coins. The demand for money evidently keeps pace with the march of civilisation, and the nude savage of to-day will have perhaps a shilling, or it may be a sovereign, in his pocket to-morrow.

Mr. Donald McKay, the eminent ship-builder of Boston, U.S., has arrived in England from America, bringing with him plans and specifications of several vessels of war, guns, &c.; for the use of some of the European naval powers. Mr. McKay has obtained permission from her Majesty's Government to visit the various dockyards of this country, and after having accomplished this, he will proceed to the Continent, visiting the dockyards of France, Austria, Russia, and the other naval Powers of Europe.

THE GREAT EASTERN'S TRIAL TRIP.*

BY A PASSENGER.

At nine o'clock on the evening of October the 7th the Burdon Hotel, Weymouth, had already begun to overflow with visitors. Each newly-arriving adventurer, no matter what his rank, was inexorably consigned for the night to the care of lodging-house keepers, scores of whom seemed willing enough to cke out the accommodation of the Burdon. The moon hung so fair above the bay, and the waters murmured so musically upon the shore, on the very verge of which the hotel and its neighbouring terraces stand, that I was pleased with an occasion for escaping from the bustle and excitement of the establishment, and with the opportunity thus afforded of enjoying the moonlit air and sea, and therefore gladly accepted an appointment to supplementary apartments.

After ascertaining from friends who had been on the spot for days that the contractors were fully prepared for the next day's departure, and that nothing but an adverse determination on the part of the directors of the company would interfere with the anticipated voyage—although the friends of Mr. Scott Russell were unanimous in urging him to seek rest from his arduous labours for a day or two before undertaking the responsibilities of the journey—I had the good fortune to meet a gentleman who had been familiar with the great ship from the first, and who up to the very evening of our conversation had performed important duties on board of her. From him I received much minute information respecting the condition in which she then was, and was pleased to find that even his critical eye had found nothing of serious importance to rest upon. During the time that had elapsed since the ship's arrival at Portland her water-tight bulkheads had been brought into a better state of integrity; an excellent suit of sails had been bent on yards and gaffs; a crew that satisfied the captain had been finally organized; the wheel-ropes had been replaced by chains, so arranged as to increase the control of the steersmen; the engines had been placed under the absolute control of the gentlemen who built them; and altogether the Great Eastern had been brought for the first time into a "ship-shape" condition. My own observations subsequently confirmed the report of my experienced friend in all important particulars, and convinced me that, although a hyper-critical person might find much to complain of, a real and earnest effort had been made to satisfy the just requirements of the press and the public.

On Saturday morning the company who were to witness the trial trip steamed from the quay at Weymouth to Portland harbour, and embarked on the largest vessel—indeed, the largest moving body of any kind—that the hands of men ever made. So much exclusiveness was displayed by the proprietors of the ship on this occasion, that the only individuals who were likely to publish scientific criticisms upon the vessel or her machinery had to get entrance afforded them by the device of an influential friend. For my own part I went on board nominally in some very responsible capacity, the nature of which I never in the least understood, and the duties of which gave me not a moment's trouble. Even the "gentlemen of the press" scarcely succeeded in securing a timely invitation, I was told. It was agreeable to observe, however, that some experienced and excellent officers of the Royal Navy had contrived to make their way on board, and would be ready to afford their aid should the necessity for it occur. Perhaps I should not exaggerate the truth if I were to say that some of the passengers also derived satisfaction from learning that we had with us a valuable life in the person of a Member of Parliament whose income is said to be about £150,000 a year,

the ground of their satisfaction probably being a vague hope that even steam and storm might hold in respect that which man so profoundly reverences.

Without the least desire to be ungracious, even in thought, I could not avoid remarking the absence of many who had shared the first trip with us, and conjecturing the cause which kept them away. How many among them had the explosion scared? I think the changes observable in the representatives of the new-papers forced this question upon me more than any other. Why was it that the journal which appeared in the form of a tall personage on the one occasion manifested itself in a short form on the other? Why did the paper that spoke Hibernian speech before speak Anglican now? How came it to pass that the organ which wore a brown shooting jacket and a sky-blue cap from the Nore to Portland appeared in a dress coat and a high hat from Portland to Holyhead? Far be it from me to believe that craven apprehensions wrought these changes. I put the questions in the full confidence that every reader will imagine for them perfectly satisfactory answers.

Between three and four in the afternoon of Saturday the anchor was weighed, and notwithstanding some small details which might be altered with advantage to this operation, the manner in which it was effected, and the perfect control which Captain Harrison exerted upon the vessel as soon as it was completed, deserved and gained the warmest approbation. Unhappily, before the breakwater was passed the dinner-bugle summoned the guests below, with a sound which few Englishmen know how to disobey, and which, in truth, was not disobeyed by many on this occasion. The departure from Portland consequently lost much of its beauty in so far as those on board the ship were concerned. To those on shore the sight was doubtless very impressive.

And truly the first movements of the Great Eastern should be full of interest for us. We have in her a mighty assemblage of machines to deal with, and to put which on its trial is no light matter. In her hull we have 8,000 tons of iron shaped into a ship, and formed to sit in the water steadily, to roll in it easily, to resist it sturdily, to divide it cunningly. In her depths we have 112 furnaces flaming, devouring more than ten tons of coal every hour, and keeping more than 400 tons of water hissing into steam. Hung at her sides we have vast wheels weighing nearly 200 tons, and turned by an engine within her with the strength of 3,000 horses. At her stern we have revolving a ponderous screw propeller on which a still greater power has to be exerted. And behind all these hangs a plate of metal by which the movements of this leviathan are to be controlled, and which has itself to be obedient to the hands of a man or two. The proportions of all these limbs or organs of the great ship are so unexampled, and the arrangements and combinations of some of them are of so novel a character, that when we see the whole of them together put upon trial we may well watch their operation with eager interest.

At forty minutes past five we passed the Bill of Portland, and stood fairly down Channel under the most favourable circumstances. During the evening a loud screaming, not unlike that of a living being, was heard to proceed from the middle of the ship, renewing itself with every revolution of the paddle-engine. This disturbance, which caused some sensation at first, was found to proceed from one of the cylinders in which a valve had got opened, the escaping steam screaming its way out into the engine-room. A little manipulation on the part of the engineers in attendance cleared the valve, and put an end to all the noise and excitement, without even so much as bringing the engine to rest. A like occurrence happened later on the voyage in the screw engine department, and was remedied with the same ease and expedition. On another occasion, the screw engines astonished some of the company by performing an air after the manner of a mellow set of bagpipes. This arose, as we soon learnt, from a loose fragment of india-rubber packing, which a

current of steam set vibrating with great rapidity, and which made music on the same principle as common reed instruments.

As night drew on, the Eddystone became visible, and having seen it on our beam about half-past eleven, my admiration of the midnight moon and sea began to flag, and I allowed "seven bells" to ring me to my berth. When I went below the weather was moderate, and on the whole fine, and even to nautical eyes no omens of change had, I believe, shown themselves. It was with some little astonishment, therefore, that after having slept but for two or three hours, I awoke to hear a high wind blowing, and to see through the dim circular glass of my cabin window, that the heavens were filled with cloud and mist, and the seas blown into a tumult of wave and foam. Thinking that a turn upon deck at such a time might prove interesting, and trusting that a careful regard to costume might be dispensed with at two o'clock in the morning in the solitude of the Channel, I speedily made my way upward, and ascended the foremost of the two bridges which extend from paddle-box to paddle-box. The Lizard lights were gleaming wildly away on our starboard bow, and not a sound was to be heard but the roaring of the wind in our rigging, the beat of the paddles on the sea, and the muffled thumping of our screw engines. Captain Harrison and one or two of his officers stood by the telegraphs that signal to the engines and helm, and on the bridge on which I stood a "look-out" or watchman paced. There was light enough to reveal this man very clearly to me, and from the moment at which I first saw him, I was struck with his absorbed and absent manner. After observing him for some time, and wondering what his thoughts were, I stepped to him and asked with affected ignorance what lights they were which we were passing. His answer being, "The Start," and I knowing they were the Lizard, and that the Start had been passed several hours earlier, nothing further was needed to convince me of the ability of this mysterious mariner. But something further, nevertheless, occurred. For presently a light began to sparkle nearly ahead of us, slightly on our port (or left) side, and from the bow a strong voice shouted—"Light on the port bow." "Light on the starboard bow," straightway cried my absorbed friend to the captain, who instantly began to peer over the starboard bow for the light. Seeing the danger of this proceeding I whispered "Port bow," in the hearing of my friend, who proudly echoed "Port bow,"—but too feebly for the captain to hear it. Meantime, we were coming rapidly up to the light, and a schooner which carried it began to show herself much more quickly than I expected. Fortunately, Captain Harrison saw her on the instant of her becoming visible, and with a lusty, "Port the helm,—hard aport," which Mr. Lungley's admirable apparatus transmitted to the stern instantaneously, contrived to turn the monster from her puny prey, and allowed the schooner to pass in safety just clear of our paddle-box. Had the Great Eastern not answered her helm admirably that night, one vessel less would have sailed the seas now, and probably half a dozen men more would have been "full fifty fathoms down," and that absent watchman alone would have been answerable for them. Why, I wonder, did that man call the Lizard the Start and port, starboard? Was it that grog had befooled his reason? Or, may he not have been a spasmodic poet inditing sonnets to the "swirling moon"? Revolving these questions I went below, and sought sleep again, with all the confidence which the circumstances of the time inspired.

Morning rose freshly and finely as morning ever rose, revealing far away to the north the sparkling Isles of Scilly. To the long swell of the seas which rolled across her path the Great Eastern yielded majestically and with a kind of motion which it may be well to mention here more particularly. On board a vessel rolling and pitching in a seaway we are made sensible of two kinds of motion—a rising and falling, and a turning partially over. The amount of the latter motion depends upon the angles through which the ship

* We could not find space for the above article (which has been in type nearly a fortnight) in our last number.

rolles or pitches, or, in other words, upon the inclinations given to her deck by the action of the sea. As the dimensions of ships are increased the effect notably is to reduce these angles or inclinations, for reasons which need no mention here. This fact was particularly observable on the morning under notice. The extremities and sides of the great ship rose and fell through considerable spaces, but the inclination of her decks was always very slight indeed. Near amidships, or the middle portion of her—in her dining saloons, for example—the motion was almost imperceptible, while the paddle-boxes at her sides, and her bow and stern likewise, moved up and down through many feet. Those who take passage in the Great Eastern hereafter may find in this fact a hint that may prove useful to them in the selection of berths.

To counteract the rolling motion which the crossing seas occasioned sail was for the first time set upon the ship. The wind came with sufficient directness upon the ship's side to render this practicable, and to keep the fore and aft sails full when set. That the sails had any other considerable effect than that of steadying her I do not for a moment believe, and I fear those who have publicly attributed to them a knot or two of the speed then made, possess very imperfect notions of the force of wind which would be requisite to add those amounts to the speed of a ship already moving at the enormous velocity of from 14 to 15 knots (16½ to 18 miles, say) per hour. Even experienced ship captains may be mistaken on this subject. The sails doubtless helped the speed to some extent by keeping the vessel steady, and thus enabling the paddles to do their work efficiently, but certainly not much in any other way. The speed attained that morning was, according to the newspaper correspondents, 14½ knots—according to the officer who cast the log, 15 knots, as I affirm from the evidence of my own senses. This was the highest velocity attained throughout the trial trip, but there is no reason why the same should not be again reached under favourable circumstances.

While the sails were being set we had a sermon preached on board, of which I had either the good or the bad fortune to hear only when it was in progress. The subject of it is said to have been the catastrophe off Hastings, and the moral of it the necessity of living in perpetual preparation for sudden death. Possibly as effective a discourse was read to us who kept the deck, and who saw beneath us the grandest product of that science which the Prince Consort extolled so nobly at Aberdeen, while around us spread the shining floor, and above us the azure dome of that "Cathedral of Immensity" in which the anthem of good men's adoration rises eternally.

Throughout the day we kept an unswerving course for the Old Head of Kinsale. When at length towards evening Ireland lifted itself blue and bright before us, it was resolved (as we passengers understood) to run and show ourselves at Cork harbour, and thus afford an opportunity for the telegraph to send to London news of the successful completion of the first half of our trip. With this view, as the sun set we took in sail, and steamed directly towards what those of us who knew not the coast believed, on very high authority, to be that harbour. Presently a nautical man of great repute, who knew the coast well, and had probably taken fleets into Queens-town harbour many times, privately advised me that we were making fair, not for it, but for Kinsale harbour! We went together to the chart, and he marked our position upon it. On reascending the deck he pointed to a headland and said:—"If we stand off a few points (which it is very desirable to do) we shall see the light of Cork harbour in about ten minutes open round that headland." The little cherub that sits up aloft may have whispered the same thing in other ears, or, which is much more to be hoped, Captain Harrison pursued steady plans of his own—and so the helm was "ported," and in ten minutes from that time the light of Cork harbour appeared beyond the headland.

By the time night had set in, and the Irish coast had become invisible, the novelty of the

voyage seemed to be wearing off. Enthusiastic men, who appeared to fancy that the fate of science was involved in every revolution of the Great Eastern's engines, went, it is true, from one engine to the other noting the number of turns made by them with a persistence which was most admirable, however useless their notes may be to them. And here I may say that a considerable deal of nonsense is practised, even by professedly scientific men, on such occasions. They act as if nothing but attention to certain superficial occurrences was requisite on their part in order to bring out all the questions which can possibly hang upon it. Whereas this is most certainly far from being correct. Many useful facts they can observe undoubtedly, and I for one gladly see them recording these; but a very little display is needed in their attainment, and the best scientific observers make no great show of their proceedings. But, apart from the gentlemen with note-books, the company lost interest in the voyage, and spent the early part of Sunday night in amusing themselves according to their several desires.

Monday was a thick and unpleasant day, and afforded but little interest to any one, until as noon was approaching the Welch coast was sighted. We had gone, (designedly, I hope,) considerably to the north of Holyhead, and after making a course "with some south in it" for an hour or more, saw first the rocks of Skerry. Holyhead itself, with the South Stack lighthouse, became visible very soon afterwards. Before entering the harbour experiments of some interest were made. Without detailing the circumstances attending them I may state their result, which was that either the paddles of the Great Eastern alone, or her screw alone, will propel the ship at a speed of from eight to nine knots per hour, the one propeller dragging or forcing the other bodily through the water at the same time. Hence, if any accident should occur to the one, the other may be relied upon to carry the ship to port, or even to her journey's end, without the use of a single sail. This is an advantage which no other passenger ship in the world possesses. How greatly it adds to her safety I need not explain.

At about three o'clock on Monday afternoon—with the pleasant but vexatious dinner bugle once more sounding most inopportunistically—we steamed past the beautiful hill side of Holyhead. The colours of this hill, or mountain, are inexpressibly rich. The whole front of the rugged rock seems to have imbibed all the brightest and choicest colours that have streamed upon it from the sunsets of unnumbered ages; and as we past close beneath it in our wondrous vessel, one could not avoid feeling that however great and beautiful the works of man may become, God will not fail to keep him humble by the sight of other works of a greatness and beauty unapproachable by him.*

With this lesson impressed upon us our voyage came to an end. Of the efficiency and economy of the great ship as tested by the trip, I shall not be expected to speak here in any technical manner. So far as her efficiency is concerned—so far, that is, as her qualities as a sea-going ship have to be concerned—she has given perfect satisfaction to every one who is capable of judging her properly. Whether she will show any marked superiority to other vessels in point of economy,

* Since the above article was put in type a paper on North Wales has appeared in the *Illustrated Times*, in which reference is made to the colours of the hills of that district in the following terms:—"Nowhere have I seen more glorious colours than those which play on the Welsh hills. Nature has formed these hills, surely, for the display of her art of colouring. In the main they are formed of limestone, but this is tinged with slaty mixture, whilst here and there pure slate peeps out. They are also metaliferous, and have in them lead, iron, sulphur, and I know not what besides; and all these metallic veins, as they show themselves on the hillsides, or by staining the water which oozing out of cracks and reefs, runs down in wayward streams over the surface of the rocks, wonderfully variegate their colours. And then, there is also the vegetation; the gorgeous heath, the brilliant yellow gorse, the mosses, and the fungi growing on every ledge and protruding from every cranny. Just fancy all this with the sun's meridian or slanting rays playing with alternate cloud shadows thereon! Sometimes to me it was so marvellous that 'it seem'd the Heavens upbreking through Earth.'"

can scarcely yet be determined, so numerous are the things which enter into this question. There is reason, however, to believe that when tried by the only tests yet in existence as means of comparing steam-ships she will take very high, probably the highest, rank. R.

THE ENFIELD RIFLE BAYONET.

THE circumstances of the time justify us in devoting much attention to the production of war-like implements. Instead of cultivating the arts of peace, we are compelled to devote our studies to those of war. As if to prove that our boasted civilisation is but a sham, we are engaged, as are all our European neighbours, in the construction of every kind of man-destroying device that the mind of man can conceive, and await but the signal to turn them to dreadful account. This is a sad complexion of affairs among nations professing Christianity, and from whose altars for century after century its holy and peaceful precepts have been promulgated. It is said, but, alas! it is true. It seems, indeed, from existing appearances, that nothing but a decided and overwhelming superiority of martial strength can save us—and we speak of England now—from the horrors of war, and that we are engaged in a race for mastery with at least one other great power of the earth. How painful soever, then, the task may be, it is necessary that we use with untiring energy the mental and the physical aids and appliances with which Providence as a nation has blessed us, in the production of death-dealing weapons. If it be a perversion of good gifts to employ them thus to apparently bad purpose, the people of England may console themselves, we think, with the consciousness that the fault is not theirs. Rifle corps are not required to protect our homesteads from internal, but external foes, and the "note of preparation" which is heard by day and by night in our arsenals and dockyards, is but the echo reverberating from beyond the channel. We do not in these days initiate war, but shall accept it as a dreadful necessity, if, unhappily, it come upon us.

Some thoughts of this nature possessed us lately when inquiring into the rate of progress made in the Government manufacture of small arms, &c., and they produced a depressing feeling. At Enfield the splendid mechanical arrangements for the manufacture of muskets are being strained to the utmost, and in London, Birmingham, and Belgium, contractors are engaged in supplementing the exertions there being made. Where this high pressure speed is to carry us—nationally speaking—it is impossible to say, we can only trust towards a safe terminus, and that the journey may be ended without an explosion! It may be remembered that not long since a description of the method of making an Enfield rifle barrel was published in our columns, and, as we have said, the interest on such matters is involuntarily on the increase, we purpose at present to pursue the inquiry into the mode of manufacturing other constituent portions of the rifle musket, commencing, for example, with the bayonet. The barrel is a dangerous weapon in the distance; the bayonet fearful in "close quarters." What is called the blade of the bayonet—the fluted, triangular, curved, bright, pointed, and handsome portion of the instrument—is made of the very best cast-steel which the art of man can produce from the natural iron. To commence with, the material to be wrought into this blade is 7 in. long and ¾ in. square. The round piece of best wrought iron for the socket, is, as it comes from the forge, 4 in. long and 1 1-16th in. in diameter. The steel to be presently "married" to the iron is, in the first instance, swaged down for the neck, leaving a swell at the bottom for welding to the socket. The working, indeed, is the next operation, and it is accomplished in the ordinary way, a little borax being used for fluxing. The amalgamated steel and iron is then taken to what is called a rider forging machine, when it is drawn out to the shape and size for machining, and has the flutings shaped to it. The machines do their mission next;

they are fitted with top and bottom swages, and work at a very rapid rate. The bottom tools are adjustable as to height, and this allows for wear and tear. The slide which holds the top tool has a very strong spiral spring acting against it, always pressing upwards. The slides are driven down upon the work to be dealt with by means of eccentrics turned out of the solid steel driving shaft, which latter is furnished with a fly-wheel, and driven at an enormous speed. There are five slides to each machine, and the springs keep them up to the fans of the eccentrics. As in the making of the barrel there were various sized grooves in the rolls between which it is passed, so in the making of the bayonet are there various sized swages with which it is successively placed before being brought near to its final dimensions. Nasmyth's steam drop is now called into requisition—for hitherto the blade has been principally operated upon—and this affects the socket, which is driven forcibly into a pair of dies. The inspector of forged work now examines the article, and, if it meet his approval, it is annealed. Next it is put through a sharp cutting die in a power-press for the purpose of removing a wire edge thrown up in the action of stamping. So ends what may be termed the smith's part of the performance.

The first operation of machining a bayonet, is to pass the socket through a succession of mills which square the ends and bring it to the proper length, and this fits it for drilling—roughly. The bayonet socket drilling machine is peculiarly constructed, and is self-acting—at Enfield, that is—and it has a chuck attached to the rising table, and which “grips” the socket firmly, while being drilled with a twisted and self-clearing drill. One boy attends easily to several of these machines. Roughly drilled in this way, the bayonet is next chucked in a horizontal boring machine—similar to a surface lathe. A half round bit of the size of the exterior of a finished barrel, is now affixed to a slide rest and made, by a self-acting feed, to pass through the socket, the result being a very perfect bore. Several minor operations intervene, and a mandril being passed through the socket, the latter is turned outwardly from “neck” to “ring.” The bayonet is next “set,” and the blade cut to length. The neck, or curved part between the blade and socket, is turned in a lathe on the copying principle. The blade and socket are now put through a series of operations, such as milling, planing, and shaping in various parts, the bore of the socket being always the fixed point to work from. The grooves or flutings are cut by revolving mills or cutters, whilst the bayonet lies beneath them in a bed, and supported from end to end to prevent chattering. The machine being put in motion, a self-acting feed carries the bayonet forward, till the mill has traversed its entire length. Fairbairn of Leeds made the principal portion of these machines. The point of the blade is now formed, and then the neck is bent. This last process perhaps requires a little explanation. A small furnace is provided into which is introduced a blast, and on the top of which is fixed a slab of fire-clay perforated with six small holes. Through these holes when the neck of the bayonet is placed immediately above them, the flame by force of blast is made to pass. The result of course is that the neck becomes intensely hot. The heat being concentrated upon the part intended to be operated upon, namely, upon the centre of the neck, it is next taken to a machine in close proximity to be bent. This machine is fitted with a stud the exact size of the bore of the socket, and upon this stud it is placed, the blade being laid across the machine. Then there is a slide into which is geared a pinion for driving it forward. This slide is furnished with a roller turned out round the edge to the figure of the blade, which it comes in contact with in moving forward, and thus forcing the neck round a stud of given diameter until it comes to a regulated stop. The socket is thus brought to its proper position, and ranging, therefore, nearly parallel with the blade. When quite cold, it is struck with great force on an anvil, in order to test the

soundness of the welding. The indentation caused by the blow is never afterwards removed, but suffered to remain as a proof of the testing.

The bayonet is now hardened, the heat being taken in a lead bath, which is kept up to a right degree of heat. When properly hot the implement of war is removed and immersed in a cistern of oil. It is next tempered and set to gauge by blazing it over a fire with oil. It is now tested throughout for strength and elasticity by springing it to the extent of $1\frac{1}{4}$ inch. If it stands this ordeal and returns to its straight position, it is passed forward to undergo other operations, one of which is to cut out the “slot” for securing it to the foresight. This is done by aid of two machines—one of which is a small ordinary slotting machine. The socket is finally coined out to gauge so as to fit accurately the muzzle of the barrel. Now it is ground on the blade, and polished for the first time, and afterwards the neck and socket are browned by oxidation. The blade is next polished as brightly as a mirror, and after some few minor operations, the bayonet passes from the hands of the workman into those of the final inspector, who omits no effort to detect an imperfection. The chances are in the proportion of 96 to 4 that the inspector will pronounce it very good, and if so it is delivered to the storekeeper for delivery into service. It may not be amiss to say something of the locking ring by means of which, as our readers know, the bayonet is attached when finished to the barrel. It is of wrought-iron, roughly forged by hand in the first instance, and then struck while hot into a die under one of Colonel Colt's screw drops. This machine has a square-threaded screw passing vertically through its centre, and is supported on four pillars. The pillars act, also, as guides for the drop hammers to slide up and down upon. There are four hammers to each machine, and thus four men may be engaged at the same time with one machine. Each hammer is fitted with a section of a nut, which is self-acting by means of springs and catches, which alternately engage and disengage with the main screw, which is driven by gearing on the top of the machine. Any amount of fall may be given to the hammer, and one blow is usually sufficient to shape the locking ring. After this blow has been struck the ring is annealed, put under a vertical drilling machine, and bored and “rimmed” out to the size of the outward diameter of the bayonet socket. It is then passed through several mills for the purpose of bringing it to the required gauge and exact figure, which being done, the hole is drilled and tapped for the reception of the screw. It is then slit through what is called the “lugs” by means of a circular saw. A little hand-labour, polishing on buff wheels, and prepare it still further, and then it is forced open to get it over the bayonet-socket. It is next blued by heating in charcoal, particular care being observed in keeping it perfectly clean by wiping with a dry rag and lime. And now the last operation comes, which is to “assemble” by carefully bending it on to the socket with a peculiarly constructed pair of tongs lined with leather, and a small box-wood mallet, care being taken not to screw it up too tightly, and it is fit for use. The total length of the bayonet when finished is $17\frac{1}{2}$ inches, and on the side facing the axis of the barrel, it is $1\frac{1}{2}$ inches across, tapering towards the end to $\frac{3}{4}$, when it takes a sudden curve of about an inch in length, and is brought to a sharp point. Taking the section of the other angle it is about $\frac{1}{4}$ ths at the shorter end, and tapered to within about one inch of the point to measure $\frac{1}{4}$ ths. It is curved outward from the barrel to clear it from any action the flame might have upon it when the rifle is discharged, and it is “fixed.” The groove of the wider side has a larger radius than that of the two narrower, leaving the edges about $\frac{1}{2}$ in. thick at the lower end of the blade. The outward diameter of the socket is one inch and its length three inches, the neck is half-an-inch in diameter at its smallest part, and cone shaped for strength at its junction with the socket.

It is hoped that the foregoing description may

make plain the *modus operandi* of bayonet forging and finishing, and that the instrument itself may hereafter be regarded with more interest—mechanically speaking—than before that description was given. It appears to be a simply-made weapon, but its manufacture is evidently somewhat complex. Like all other parts of the Enfield rifle, its parts are interchangeable, and any bayonet and locking ring will fit any musket made at the Government works.

Contractors have not as yet, from want of machinery and appliances, been able to supply rifle muskets of an interchangeable character, nor yet at as cheap a rate as those prepared at Enfield. Birmingham has striven to accomplish these desiderata but has hitherto signally failed, and as at the first-named place, from the vigilant activity of Colonel Dixon and his officers, there are continual improvements being made in the machinery department, it is most likely that Birmingham, with all its “go-a-head” competitiveness, will lag behind in the race for some time longer.

Literature.

A Manual of Naval Tactics: together with a brief Critical Analysis of the principal modern Naval Battles. By JAMES H. WARD, Commander U.S.N., Author of “Ordnance and Gunnery,” and “Steam for the Million.” D. Appleton and Co., New York, and 16 Little Britain.

THIS is, we are informed, a primer or first book, for the purpose of making the study of naval tactics easier and more inviting. It consists mainly of a digest of standard works on the subject, and of original analyses of some of the most famous sea-fights. It was written while the author was “in command of a corvette on the coast of Africa, where it served to beguile leisure, and relieve the tedium of service in that torrid region.”

The choice of such a pastime in that horrid region was laudable enough, especially as it gave the author an opportunity of dedicating a book to Governor Toucey, the Honourable Secretary of the Navy, but the book itself seems to us to be without merit of any kind.

The first section describes the “orders of sailing,” and the manœuvres of sailing fleets. The second treats of engagements under sail. The third, of engagements between fleets at anchor. These, with the conclusion, occupy 127 pages.

Then follows the fourth section, consisting of nine pages on “Tactics under Steam.”

The excuse for writing such a book in this day of steam fleets is that “as officers, notwithstanding steam, must still be seamen, and understand the art of manœuvring a single ship under canvas, so also must they continue to study the art of manœuvring an assemblage of ships under canvas—in other words, naval tactics as here presented. And, on the contrary, when officers need no longer be seamen, neither will they need any longer to understand tactics under sail.” Commander Wood says that “the language has been graced” by Sir Howard Douglas’ “Naval Warfare with Steam.” We are sorry that it is so utterly impossible to pass the same compliment upon him. Some of his writing is very discreditable; take the following sentence for example:—“In the British and French naval operations for the last hundred years, the latter—a chivalrous, yet not so decidedly a maritime nation—appears from policy to have adopted the practice of gaining the wind to avoid decisive engagement; and the former, for very obvious reasons, the reverse—that is, for position to attack.” And in describing the battle of Camperdown, he says:—“Admiral Duncan's action (Lord Duncan in consequence) was fought in 1797, against a Dutch fleet, off Camperdown, coast of Holland,” “with a most brilliant and decisive result,” “for notwithstanding close to their own coast, but few of the Dutch escaped.” His thoroughly Yankee style of criticism is very amusing. See how he opens fire upon poor Lord Nelson with reference to his general orders issued from the Victory, off Cadix, October 18th, 1805, *i.e.*, on the eve of the battle of Trafalgar. One of

the clauses of these orders, which he gives entire, runs thus:—

"The impression of the *whole* British fleet must be made, with the intention of overpowering it, in that *portion* of the enemy's line rearward from the third or fourth ship ahead of its commander-in-chief, presumed to be in the centre. I will suppose the twenty enemy's ships ahead of this point in the line to remain untouched. It would be some time before they could manœuvre to bring their force compact to attack any part of the British fleet, or succour their own rear, and it would be impossible without mixing with the ships engaged."

Here our author breaks in within brackets:—"Well! pray if one party mixes, doesn't the other get mixed? Whatever the evils, certainly they attach equally to one party as to the other. One loses patience with the idea that all evils are on one side, an idea which seems to have always engrossed both the English and their European enemies."

The following remarks are interesting as an American view of our naval position and duties:—

"But whatever is to be the constitution of the future fleet, it must not be forgotten that from the days of ancient Rome to those of modern England, from Actium to Lepanto and Trafalgar, the empire of the world has depended upon and followed, and has been lost and won with, the empire of the seas; and that this empire always has been, and always will be, contested with large fleets, little influenced by the guerilla fighting of single ships. Comprehensive minds, therefore, in devising naval construction, will look to such a combination of ships as shall produce the most effective fleet in this great contest for dominion which must one day come off—none can tell how soon. Not that fleets should be held in preparation, or even constructed, for so indefinite an event; for it is idle, as it is unreasonable, to look on a continental nation as the United States for the living perpetual interest and favour with which an insular people, like those of Great Britain, cherish their wooden-walled defences, and patiently endure the burdens they entail. But such a degree of experimental construction as will determine the best types is judicious; because with men, money, and material at command, it renders the problem of sudden and indefinite increase in the number of ships of easy and safe solution in the event of war. And however politic or fashionable it just now is to laud the actual construction in France as evidence of her comparative naval strength, it is in reality *resources* for building, equipping, and manning ships, in which England vastly excels, that gives to her, or to any nation possessing them in the greatest degree, a true and actual maritime ascendancy."

We think the subject of naval tactics is at this moment of the very first importance, and ought to occupy the attention of the Government. While the Board of Admiralty still remains inert, and gives no sign, in spite of all Sir Howard Douglas' adjurations, the French Ministry of Marine has prepared an elaborate system of tactics for steam warfare, and is carefully instructing in it the men who may one day dispute with us the sovereignty of the seas.

Proceedings of Societies.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary meeting October 4th, 1859.—William Fairbairn, Esq., F.R.S., &c., President, in the chair. The President delivered an address on the occasion of the opening of the session. He commenced by adverting to the loss which had been sustained by the Society by the death of two of its ordinary and two of its honorary members. Mr. Laurence Buchan, the oldest member of the Society, died at the advanced age of eighty-four years. Mr. John Ashton Nicholls, F.R.A.S., was suddenly called away in the prime of life. The honorary members who have passed away are

Alexander von Humboldt and the Rev. William Turner. The President reviewed the past history of the Society, pointing out what had been accomplished by the members, and the path still open for successful scientific research. He adverted to the great advances made in recent times in all the departments of knowledge. In conclusion he congratulated the Society on its prosperous state, and expressed the fullest confidence that the members would, by their contributions to literature and science during the present session, fully maintain its reputation. The thanks of the Society were voted to Mr. Fairbairn for his excellent address.

Dr. F. Grass Calvert presented, on the part of Mr. Appender, of Turin, a paper containing "Researches on several Organic Colouring Matters."

A paper by Mr. John Smith, M.A., was read by his brother, Dr. R. A. Smith, entitled "On the cause of Colour and the Theory of Light." The author, in attempting to explain certain natural phenomena, could not satisfy himself by applying the principles of either theory of light. A series of experiments was subsequently undertaken, which led to the conclusion that varieties of colour are produced by pulsations of light and intervals of shadow in definite proportions for each shade of colour. That is, supposing white light to consist of the motion of an ether, blackness to consist of entire absence of motion, then a certain colour, blue, red, or yellow, will be produced by the alternate action of the light and the shadow. The author used shadow in the positive sense as the sensation was positive. He considered that his theory gave an entirely new and simple explanation of the phenomena of refraction through the prism, and summed up as follows:—"The experiments prove the homogeneity of the ether. They prove the undulatory hypothesis, but oppose the undulatory theory. They enable us to dispense with the different refrangibilities of the rays of light, as taught by Newton. They help to explain many of the phenomena of what is called the polarization of light. They give a new explanation of prismatic refraction, and explain in a plain and simple manner many very interesting natural phenomena." Startling, he said, as these conclusions are to those who are conversant with the subject of light, he thought he was perfectly warranted in drawing them from his experiments. The general process of reasoning could not, however, be given in a short abstract.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY.—*Geological Society.* Papers to be read.—1. On the passage-beds between the Upper Silurian into the Old Red Sandstone at Ledbury, Herefordshire. By the Rev. W. S. Symonds, F.G.S. 2. On the Coal Formation at Auckland, New Zealand. By Henry Weekes, Esq. 3. On the Geology of Vancouver's Island. By W. Bauerman, Esq.

EXPERIMENTAL RESEARCHES TO DETERMINE THE DENSITY OF STEAM AT ALL TEMPERATURES.

By WM. FAIRBAIRN, F.R.S., and THOS. TATE, F.R.A.S.*

I propose to give a short sketch of an apparatus, and the results of the earlier experiments which, in conjunction with my friend Mr. Thomas Tate, I have been investigating by direct experiments, with the intention of determining the law of the density of steam and other condensable vapours; and thus to solve a hitherto almost untouched problem by an experimental method, which will verify or correct the theoretical speculations in regard to the relation between the specific volume and temperature of steam and other vapours. The experiments are being conducted, it is believed, upon an entirely novel and original principle, and one which is applicable at any temperature and pressure capable of being sustained by glass vessels.

For a perfect gas, the law which regulates the

relation between temperature and volume is known as Gay-Lussac's or Dalton's law, and is expressed by the equation:—

$$\frac{V \times P}{V_1 \times P_1} = \frac{458 + t}{458 + t_1} \dots\dots (1).$$

Now, density of steam has been determined with accuracy by direct experiment at the temperature of 212°—and at that temperature only—by the method of Dumas. At 212° Fahrenheit its density is such that its volume is 1,670 times that of the water which produced it. Hence, assuming Dalton's law to hold for steam, and substituting these values of volume, temperature, and pressure, we get for the volume of steam from a unit of water at any other temperature:—

$$V = \frac{1670 \times 15}{670} \times \frac{458 + t}{P},$$

$$\text{Or, } V = 36\frac{1}{2} \frac{458 + t}{P}, \dots\dots\dots (2).$$

These are the well-known and received formulæ from which all the tables of the density of steam have hitherto been deduced, and on which calculations on the duty of steam-engines have been founded. Up to the present time, however, this formula has never been verified by direct experiment, nor are the methods hitherto employed in determining the density of gases and vapours applicable in this case, except at the boiling temperature of the liquid at the ordinary atmospheric pressure. But, on the other hand, theoretical speculations throw considerable doubt on the accuracy of the above formula when applied to steam and other condensable vapours. Several years ago, Dr. Joule and Professor William Thomson announced, as the result of applying the new dynamical theory of heat to the law of Carnot, that for temperatures above 212° Fahrenheit, there is a very considerable deviation from the gaseous laws in the case of steam. Later, in 1855, Professor Macquorn Rankine has given a new theoretical formula for the density of steam, independent of Gay-Lussac's law, and confirmation of Professor Thomson's surmise. But as yet these speculations need the evidence and verification of direct experiment.

The density of steam is ascertained by vapourising a known weight of water in a glass globe of known capacity, and noting the exact temperature at which the whole of the water becomes converted into steam. From these three elements,—volume, weight, and temperature—the specific gravity is known. But in pursuing this method, these two difficulties must be overcome. First, the pressure of the steam renders it necessary that the glass globe should be heated in a strong and consequently opaque vessel. Second, as steam rapidly expands in volume for any increase of temperature beyond the temperature of saturation, it would, in any case, be impossible to decide by the eye the temperature at which the whole of the water became vaporised. The temperature of saturation, or temperature at which the whole of the moisture is converted into steam, whilst no part of the steam is superheated, must be determined with the utmost accuracy, or the results are of no value.

The difficulties thus resolve themselves into finding some other test of sufficient accuracy and delicacy to determine the point of saturation. This has been overcome by what may be termed the saturation gauge; and it is in this that the novelty of the present experiments consists.

To illustrate the principles of the saturation gauge, suppose two globes A and B, Fig. 1 (next page), connected by a bent tube containing mercury at a b, and placed in a bath in which they can be raised to any required temperature. Suppose a Torricellian vacuum to have been created in each globe, and twenty grains of water to have been added to a, and thirty or forty grains to B. Now, suppose the temperature to be slowly and uniformly raised around these globes; the water in each will go on evaporating at each temperature, being filled with steam of a density corresponding to that temperature, and the density being greater

FIG. 1.

as the temperature increases. At last a point will be reached at which the whole of the water in globe *a* will be converted into steam, and at this point the mercury column will rise at *a* and sink at *b*; this is the saturation test, and the cause of its action will be easily seen. So long as vaporization went on in both *A* and *B*, and the temperature was maintained uniform, each globe would contain steam of the same pressure, and the columns of mercury, *a* and *b*, would remain at the same level. But so soon as the water in *a* had vaporized, and the steam began to superheat, the pressure in *a* would cease to remain uniform with the pressure in *B*, and the mercury column would at once fall, and thus indicate the difference. The instantaneous change of the position of the mercury is the indication of the point at which the temperature in the bath corresponds with the saturation point of the steam in *a*.

To show the delicacy of this test, I may instance that at 290° Fahrenheit, the mercury column would rise nearly two inches for every degree of temperature above the saturation point, as the increase of pressure arising from vaporization is twelve times that arising from expansion in superheating at that point, and a similar difference exists at other temperatures.

The apparatus, as employed for experiment, varies according to the pressure and other circumstances of its use. Fig. 2 represents one of the arrangements which has been employed with suc-

FIG. 2.

WALKER'S PATENT FRICTIONLESS STEAM BOILER FLOAT.

WALKER'S PATENT FRICTIONLESS STEAM BOILER FLOAT.

SIMPLICITY of arrangement is of vital importance in all boiler fittings. The lives of so many depend upon them that we receive all real improvements in their construction as matters of considerable importance. The old stone float, with its counter-balance weight, its suspension rod, gland, and steam-tight packing, the friction of which materially impairs the certainty of its action, is for this reason a doubtful indicator, and should never be used in its old form without the boiler to which it is fitted having an adjunct in the shape of a glass gauge. Were it not, however, for this objection of friction the float in question would be all that we could desire as an indicator. Mr. Walker, of Birmingham, has in a very simple manner overcome the difficulty, and produced a remarkably sensitive float. It has now been in action some time, and has never been known to fail, so that we have confidence in laying it before our readers as a practically good thing.

Walker's patent frictionless float consists of a lever enclosed in a cast-iron box made in the form of a segment of a circle. The end of the lever on which it vibrates is fitted with a spindle, which passes through one side of the box, and carries on its outside end another lever extending in a line with the inside one as a pointer, and the other way to receive a weight to balance the float. To the vibrating end of the lever situated inside the box is attached a copper chain, which passes down a pipe bolted to the top surface of the boiler, and forming a standard to the segmental box; to the lower end of this chain is suspended the float of ordinary form. The chain is also carried up from the internal lever to a brass plug, which forms a valve at the lower end of a whistle situated at the top of the segment. When the water is the right height in the boiler the chain hangs loose, but if it falls too low the tension pulls down the plug or valve, which is held by a spring in its place, and an alarm is sounded. On referring to the engraving of the sectional elevation, the various parts will be seen in position; *A* shows the segmental box, *B* the internal lever, *C* the chain leading to float, *D* chain leading up to whistle valve, *E* the whistle and valve, *F* the external lever and balance weight, with the external pointer in a line with the internal lever.

By the side of this section is an end elevation, which completes the delineation.

Arrangements for the reception of the Great Eastern, which is expected to arrive at Southampton from Holyhead early next week, are in active progress. As stated in the *Times* of this morning, the moorings will be furnished from Portsmouth dockyard by Admiralty order, and they will be laid down off Fawley beacon, about four miles down the Southampton Water, where the great ship will have plenty of room to swing freely at all times of tide. The anchors, blocks, chains, pendants, and bridle to form the moorings for the great ship in Southampton Water, were yesterday selected in Portsmouth Dockyard, and will this morning be shipped on board a Government lighter for conveyance round.—*The Times*, Thursday.

cess. It consists of a glass globe of about seventy cubic inches capacity, in which is placed, after a Torricellian vacuum has been formed, the weighed globule of water. The globe with the stem is shown at *A*; this is surrounded by a copper boiler *B*, prolonged by a stout glass tube *C*, enclosing the globe stem. This copper boiler forms the water and steam bath through which the globe is heated, and in fact corresponds to the second globe *B*, in the former figure. The fluctuating mercury column, or saturation gauge, is placed at the bottom of the tube *C*, and the saturation point is indicated by the rise of the inner mercury column *a*, and the fall at the same time of the outer mercury column *b*. As soon as the whole of the water in the globe *A* is evaporated, there is an instantaneous rise of the inner mercury column to restore the balance of pressure, and that progressively with the rise of temperature.

As an auxiliary apparatus the boiler is provided with gas-jets, *E*, to heat it, and with an open oil-bath *G* to retain the glass tubes at the same temperature as the boiler, and this oil bath is placed on a sand bath, and also heated with gas. A thermometer *D* registers the temperature, and a pressure gauge *F* the pressure of the steam; and a blow-off cock *H* serves to reduce the temperature when necessary. A number of results have already been obtained, but they are not yet sufficiently advanced to be made public. The following numbers have been, however, approximately reduced from the theoretical formula above, and the experimental results may illustrate the use of this method of research. The most convenient way of expressing the density of steam is by stating the number of volumes into which the water of which it is composed has expanded. Thus one cubic inch of water expands into 1,670 cubic inches of steam at 212° Fah., into 882 cubic inches at 251°, and into 400 cubic inches at 301°, and so on; in this way the following numbers have been computed:

Temperature	Volume of Steam.	
	By Formula.	By Experiment.
214°	1,005	896
245°	969	890
257°	790	851
262°	740	830
268°	680	833
270°	660	804
283°	540	480

These determinations at pressures varying from ten to fifty lbs. above the atmosphere, are not accurate reductions from the experimental results, but only approximations. But they uniformly show a decided deviation from the law for perfect gases, and in the direction anticipated by Professor Thomson, the density being uniformly greater than that indicated by the formula. I hope by the time of the next meeting of the Association, with the assistance of my friend Mr. Tate, to be enabled to lay before the section a series of results which will fully determine the value of superheated steam, and its density and volume as compared with pressure at all pressures, varying from that of the atmosphere to 500 lbs. on the square inch.

TYSSSEN'S APPARATUS FOR INDICATING THE SPEED OF SHIPS.

FIG. 1.

FIG. 4.

FIG. 3.

FIG. 2.

TYSSSEN'S APPARATUS FOR INDICATING THE SPEED OF SHIPS.

Mr. JACOBUS TYSSSEN, of Rotterdam, in the kingdom of Holland, mariner, has just patented in this country an "An Improved Apparatus for Indicating the speed of Ships and other Vessels." He fits inboard on the axis of a three-bladed screw which is placed outside the vessel a wheel which gears into one or more wheels, and causes the last in the train to make, say, one revolution when the vessel is progressing at the rate of ten knots an hour, which revolution is shown upon an indicating dial. He does not confine himself to wheels made to work and show this speed only, the invention consisting in indicating by means of registering wheels placed inboard, the revolutions of a screw working in the water fitted on the axis of the first wheel in the train, the train of wheels being set to show so many knots per hour on the indicator according to the revolutions of the screw in the water. Fig. 1 of the accompanying engravings is an exterior front elevation of an apparatus for indicating the speed of ships and other vessels constructed according to this invention; Fig. 2 is a view with the front plate removed; and Fig. 3 is a side elevation of the apparatus with the exterior case removed. *A B* are two metal plates held together by rods *C C C* secured to the front plate by washers and screws as shown. The plates *A B*, with the mechanism they hold between them, and about to be described, are placed in an outer case *D*, which is suspended by a lug *E* to the side of a ship's cabin, or the stern of a vessel, on deck, or in any other convenient position. *a* is the main spindle, from which the whole motion is derived; the outer end of this spindle carries a link and eye to which a line is attached, which line carries at its extremity a three-bladed screw, a view of which is given at Fig. 4, but the patentee does not limit himself to this form of blade. As the vessel moves through the water, this screw revolves, which through the line attached to it gives motion to the spindle *a*, and this through wheels and pinions indicates on a dial or dials the speed at which the ship is travelling, as is about to be explained. The spindle *a* carries a pinion *b*, which gears into a wheel *c*, supported by a bracket *d* screwed to the back plate *B*. The shaft that carries the wheel *c* also carries a pinion *e*, which gears into a wheel *f* containing the same number of teeth as the wheel *c*. This wheel *f* is supported by a bracket *g*, and the shaft which carries the wheel *f* also carries a pinion *h* that gears into a wheel *i* on a shaft *k*, which carries a pointer *l* that revolves round a dial plate *m*, which when it has made one revolution shows that the

ship has run one knot. The shaft *k* also carries a pinion *n*, which gears into a wheel *o* on a shaft supported by a bracket *p* screwed to the front plate *A*. This shaft carries a pointer that revolves round a dial plate *q*, and indicates when the ship has run from one to ten knots. The shaft which carries the wheel *o* also carries a pinion *v* that gears into a wheel containing the same number of teeth as the wheel *o*. The shaft which carries this wheel *s* is supported by a bracket screwed to the front plate *A*, and carries a pointer *w* that revolves round a dial plate *v*, and indicates from ten knots to a hundred the distance the vessel has run; *w* is a tube for the passage of oil to lubricate the spindle *a*. The patentee has shown the apparatus to indicate up to a hundred knots the distance a ship has run, but without departing from the invention the apparatus can be arranged to show any other number.

ROBERTSON PATENT CHAIN-PROPELLER.

By Mr. PETER SPENCE.*

At the request of the patentee and several gentlemen engaged in bringing this invention into practical operation, I have undertaken to give a short description of it to the mechanical section of the British Association.

As mechanics is a department with which either theoretically or practically I am only very slightly acquainted, I hope the members of this section will look charitably on my efforts if I fail in giving a lucid description of what seems to be an invention displaying considerable ingenuity, and of great practical importance.

It is well known that great efforts have been made to adapt steam power to the conveyance of both passengers and goods on canals, but although the failure of most of these efforts is apparent, from the fact that on a very few canals is it at this moment employed, yet there seems no reason to doubt that if steam power can be made to suit itself to the peculiarities of canal navigation, it will be found, as in every other department of mechanics, the cheapest and most convenient agent.

In 1831, when the first efforts seem to have been made to employ steam power on canals, Mr. Fairbairn, who then engaged in an extensive series of experiments by which much valuable data was elicited, recommended for this purpose a peculiar form of steam-boats with paddles in the stern; but however well these boats might other-

wise have fulfilled the design, the surge from every form of paddle steam-boat was no doubt the fatal barrier to their adoption. When, at a later period the screw was adopted as a propeller, this seemed to meet the difficulties of the case, and screw-propelled boats have to some extent been adopted and are now in use; but even the screw has been found only applicable to the few canals which are of considerable depth; and in these the danger always exists of a disturbance producing a disintegrating effect on the sides and bottom of the canal, and where, as in the majority of canals, the depth does not exceed three to four feet, the working of the screw is found to be altogether impracticable.

The invention of Mr. Robertson fully meets and obviates these difficulties arising from the use of both the paddle and the screw, while it possesses advantages in obtaining the full effect of the power applied, which are apparent at once. In whatever mode power is applied to the propulsion of vessels in water, by the paddle or screw, there is a great loss of power, only a part being productive and the remainder wasted. For example, when the paddle is just entering the water on the one side, and leaving or emerging from it on the other, the powers expended in these actions only neutralise each other, and contribute nothing to the propelling of the vessel. So great is the loss of power in some circumstances, that one authority gives the following example: suppose a boat propelled in a stream, the power being affixed or applied to a cylinder, on which a rope is wound, the other end of the rope being attached to a fixed point at some distance up the stream or on shore, and that the power is afterwards applied by paddles in the stream; it will, he says, take three times the motive power in the latter case than it does in the former to propel the vessel at the same speed. This, I think, must be an exaggerated estimate; but it clearly proves the great loss of power in certain cases, and the probability that it is considerable in all.

The peculiar principle of Mr. Robertson's invention is, that he applies the power by dragging the vessel from a fixed point, and its great ingenuity is, that the fixed point is at the same time a moveable one, a constantly fixed point in relation to the power exerted by the engine in propelling the vessel, and a constantly changing point in relation to the course on which the vessel is being propelled. The construction of the propelling apparatus is as follows:—At or near the bows of a boat, say 70 feet long, is placed a steam-engine, the main shaft of which crosses the bows of the vessel at or about the level of the deck; and

* British Association, 1859.

fixed pulley is attached to each end of this shaft, these pulleys projecting over the sides of the vessel; they are three feet or more in diameter, and on their periphery have a hollow or groove to receive the chains which are to run over them; they are also so constructed as to take a firm hold of the chains as the power is exerted in dragging the chains over the pulleys. On the other or the stern end of the boat are two pulleys, also projected over, one on each side; these are loose, so that the chains merely run over them. Friction rollers are also placed along each side of the vessel, to carry the chains as they pass from the stern to the bows of the vessel; the chains, which are endless, pass or are dragged over fixed pulleys at the bow of the vessel, and falling down lie along the bottom of the canal, and thus become the fixed point or lineal anchor on which the power acts; the action of the engine in dragging the chain over the loose and fixed pulleys being necessarily to drag or propel the boat forward. Every yard of the chain passed over the pulleys representing a yard of space that the boat has progressed in her course—the fixed point or length of chain lying at the bottom of the canal still remaining the same, what is taken up at the stern being replaced by exactly the same length deposited at the bows. The speed of the vessel is thus exactly equivalent to the speed and size of the driving pulleys, unless, indeed, there should be any slip of the chain in passing over them, and this in practice is easily prevented, and is again exactly measured by the velocity of the chain, unless there should be a slip of the chain along the whole length over the bottom of the canal, and this, of course, is a mere matter of the weight of the chain. In repeated trials which have been made before thousands of spectators (and in more than one of which the writer was on board), in a boat 70 feet long and 7 feet wide, the chain used was only 20 lbs. per yard, or 40 lbs. per yard for the two chains, 22 yards of double chain being always at bottom; this gives a weight or resistance of 880 lbs. in this case as the fixed point. From the data ascertained by Mr. Fairbairn, that in tugging vessels the average pull of a horse was 91 lbs., the fixed point in these trials would exceed nine horses' power, and an engine power of nine horses could therefore be exerted with out the chain slipping over the bottom of the canal. The speed attained ranged from four to six miles per hour, and nothing more was attempted at that time; the motion was easy and regular, the facility for starting equal to either screw or paddle, and the power of stopping quite peculiar. The moment the engine stops she drags at anchor, and the momentum is absorbed before the vessel has proceeded one-half of her own length. The weight of chain can be doubled or quadrupled without inconvenience, and the capability of using increased power to any extent be afforded as required. The weight of chain when increased does not materially increase the loss of power, as the power expended in raising the chains at the stern is neutralised by the weight of the falling chain at the bows, the only loss of power being the friction on the pulleys and friction rollers as the chains pass from stern to stem of the boat above water, and that must be so trifling as not to merit calculation. The invention is not limited in its application to canals, but is suited to rivers where occasional shallowness may render either paddles or screw useless, or where a strong current would prevent any amount of power being got except at an enormously increased and therefore impracticable speed. No additional speed but only an additional power would be required by the chain propeller to stem the strongest current, and however shallow, if the boat will float the propeller will work.

It is almost needless to add that the working of the chain gives rise to none of that commotion in the water that constantly attends the working of both paddles and screw; the chains rise and fall without the least perceptible agitation of the water, and even the ordinary wave from the bow of the boat is cut in pieces by the falling chain and reduced to the merest ripple.

THE DEEP-SEA PRESSURE GAUGE.

By HENRY JOHNSON Esq.*

THE few experiments which I have made on the compressibility of water by pressure, show a greater than indicated by Mr. Carston of 1 in 21,710 for the pressure of one atmosphere. The method adopted is that of subjecting to the pressure of a column of mercury a bulb of water on the short end of an inverted glass syphon, containing eight ounces of water, ninety-nine parts in the bulb and one part on the tube, which is divided into 100 degs., so that each degree is of the whole 1-10,100th part, and the pressure of each 30 in. of mercury caused a compression of rather more than 1 deg. in fresh water, and about $\frac{3}{4}$ of a degree in sea water. The result varied a little owing to the effect of slight variations of temperature on the bulb. This difference of result, however, does not affect the principle of the instrument. The compressibility of water is too minute to be recorded in a simple tube, but it may be recorded in two methods; one, with a bulb or bottle and a tube accurately divided, the tube being furnished with an index to be pushed along the tube by a cork or elastic piston isolating the water in the vessel, and travelling along the tube towards the bulb during the descent until the isolated water became equally dense with the water surrounding it, and when pushed back in ascending by the expanding water in the bottle, leaving behind the index to mark the degree of compression, a small aperture at the end of the scale allowing the escape of the air confined by the cork or elastic piston. The instrument to be fastened to a line with the piston downwards, so that the isolated water, being lighter than surrounding water, should press upwards against the tap rather than towards the piston. Another method of applying the principle has, however, been adopted on the suggestion of Mr. F. Hoffman, who made the instrument; namely, to have a tube or cylinder of metal, and in lieu of a scale tube, to use a long bolt of metal, or, in other words, a long solid metal piston to enter the cylinder through a packing box, and to be pressed into the cylinder by the external pressure of the superincumbent water. In descending the piston, when pressed into the cylinder until the density of the isolated sea water equalled that of the sea water surrounding it would draw along an external scale an index recording the compression; and on ascending, the piston, when pushed back by the expansion of the isolated water, would leave in its position the index fixed by a spring acting on a toothed rack at the side of the scale. In this form the action of the instrument appears to be very simple—the piston being pressed into the cylinder, or out of it, according to the relative density of the water in the cylinder and of the water surrounding it; and resemble the action of some other hydraulic presses, although this instrument is worked by the pressure of the sea, and others by the hydraulic pump. After a correction for the effect of the friction upon the piston in the packing box, and which is considerable, the instrument appears to record the density or compression of the sea water surrounding it—and consequently the pressure to which telegraph lines would be subjected at the same depth.

An experiment of great interest might be made by sending down with this instrument a deep sea thermometer, and deducting from the total amount of compression, the compression resulting from variation of temperature between the temperature of the water and the surface and at extreme depths, and comparing the balance of compression with the depth as indicated by careful soundings, or with some approved instrument, as, for instance, Massey's sounding instrument. Some further experiments will be required to ascertain the effect of variation of temperature on the capacity of the cylinder; and any correction that may be necessary. An endeavour has been made to demonstrate practically the compression of water by screwing a small cross-bar into the end of the piston and attaching weights to it, but as the instrument is

without the support of the external pressure of the sea water, which would balance the internal pressure, and has not been strengthened for the present experiment, this experiment must be considered not as an exact experiment, but simply as an illustration of a principle; the amount of compression being greater than that indicated by the previous experiments.

The vessel is made of cylindrical form in order to allow some length for the piston and scale, and it contains exactly 10 ounces of water. The piston is of such a size that 26 in. would displace one ounce of water, and is divided into 100 principal degrees, which are subdivided, each principle being 1-1000th part. Of this length a portion of 40 deg. (about 10 in.) has been taken, so that this instrument can record compression up to the extent of 40 parts in a thousand. A spanner accompanies the instrument, to unscrew or tighten the packing box when necessary; the other end of the spanner fits into and turns a tap at one end of the cylinder, the interior of which is oval, and the tap has a small air channel to allow the escape of air, so that the cylinder may be filled quite full of water. The instrument may then be placed in the accompanying stand, and the cross bar screwed on to the piston, and weights attached to the cross bar showing pressure after deducting the weight of the two 2 lb weights, together 4 lb., which are required to overcome the friction on the piston in the packing-box, when the cylinder is empty. The spring should be relaxed, and the index pressed down a little, and afterwards pushed up to the piston to prevent the friction of the index from affecting the experiment. If the two 5 lb. weights, together 10 lb., are used after deducting the 4 lb. for friction, a pressure weight remains of 6 lb. The diameter of the piston being $\frac{1}{4}$ ths of an inch, the area is about $\frac{1}{16}$ th part of a square inch, and the pressure of the 6 lb. upon the piston is thus equal to a pressure of 84 lb. per square inch.

It is to be hoped that after some further experiments to ascertain the effect of variation of temperature upon the capacity of the cylinder, and any correction that may be required, that the instrument will be found practically useful.

ON THE TRUE ACTION OF WHAT ARE CALLED HEAT-DIFFUSERS.

By ARTHUR A. TAYLOR, of Manchester.*

MR. WYE WILLIAMS and others have found that an increased effect was produced by the fuel burnt in steam boilers when what have been called heat-diffusers were placed in the tubes or flues. The apparatus in question consists generally of metallic bands or ribands twisted into spirals or bent in the direction of their length into zigzag forms, and placed in the tubes or flues, the professed object of this addition being to break up or disturb the current of heated gases passing through the tubes, and to cause every portion of the gases to impinge on the heating surfaces. The cause given for the increased effect produced being, that when a current of heated gases passes through a tube under ordinary circumstances, only the exterior portions of the columns come in contact with the sides of the tube, and that in thus disturbing the current by obstacles to its direct course, a more perfect contact of the gases with the surfaces is produced. The question which I wish to raise is, whether this is the true explanation of the effect produced by diffusers, deflecting bridges, &c. I think it can hardly be admitted that each molecule of a gas passing through a tube follows a course parallel with the axis, for those in contact with the sides of the tube will be so impeded by friction as to have a much slower motion than those in the centre, just as in a river the current near the banks is less rapid than that in the middle of the stream; and, that as in the river, so in the tube, a series of eddies will be formed, tending to bring all portions of the gas in contact with the sides of the tube. This peculiar motion of gases in a tube may very clearly be observed in the smoke issuing from the funnel of a

the smoke retaining the eddying motion had in the funnel for some time after

These considerations led me to consider disturbance of the currents as to explain the increased evaporation and to attribute it to a very different cause, do not radiate the heat which they, that the only mode in which a gas can take its heat to a surface is by contact or conduction. This is in the present practice the case in which those heating surfaces of a boiler are not exposed to the radiation of a flame, can abstract heat from the combustion; but if in a flue or tube a gas is introduced, it will become heated by the gases, and will radiate the heat received to the sides of the flue. Now, if the tubes, &c., exactly fulfil these conditions, they will, therefore, attribute their effect mainly, if not solely, to the function which they must perform in absorbing heat from the gases by contact, and radiating this heat to the sides of the flues, and I think it will be admitted that the rate of heat thus conveyed to the water is very important, when it is considered that the temperature of the gases in the tubes of a boiler is 6 in. or 6 ft. from the fire-box tube-plates 800 deg. Fah., and that these radiators frequently have a temperature of several degrees above that of the surfaces in contact with the water in the boiler, and that a very small radiation must consequently take place to the other. This principle once understood, the modes of application in practice are endless, and I will only mention that I have seen any advantage in making these radiators of such a form as to impede the passage of the gases, especially in the case of marine boilers, I rather choose the form which would present the greatest amount of radiating surface, and the least impediment to the free passage of the gases, sets of combustion through the tubes. An effective form as any for placing in the tubes of boilers would be a simple straight tube, or a wider band bent in the direction of the breadth, at an angle of 60°. In the case of marine boilers, they should be made so as to enable the tubes to be swept.

BASTIER'S PATENT PUMP.

A full description of an improved chain pump, the invention of M. Bastier, has been sent to the Editor of the Mechanics' Magazine. The pump now employed in the Royal Arsenal is a tube of uniform diameter, and is furnished with leather washers. Its principle is, namely:—1. The resistance caused by the leather discs against the inner surface of the tubes. 2. The rapid decay and alteration of the leather discs, which cannot be replaced. 3. The loss of the water in the spaces left empty by the ascending water, and consequently loss of motive power. In T. O. Bastier's new pump-elevator the tube is of unequal diameter, that is to say, some parts at a certain distance from each other are of a slightly smaller diameter than the others. This peculiar disposition is a great improvement. It replaces the leather discs, and keeps the column of water suspended by each disc passing through the smaller diameter, produce sufficient 'aspiration.' Besides, the leather discs are furnished with three superior-rubber washers of different diameters, their permanent elasticity are in contact with the inner part of the tubes, and are constantly filled. The discs being out one yard from each other, it has been ascertained that the resistance was sufficient to render the action of the pump easy and effective.

Following statements are made as to the merits of the improved pump:—"1. It is from 90 to 92 per cent. of the motive power. 2. Its price and expense of 'installation'

are 75 per cent. less than the usual pumps employed for mining purposes. 3. It occupies a very small space. 4. It raises water from any depth with the same facility and economy. 5. It raises water with the water, and without the slightest injury to the apparatus, sand, mud, wood, stone, and every object of a smaller diameter than its tube. 6. It is easily removed, and requires no cleaning or attention."

The pump may be seen at Mr. W. P. Warners, Welsh Harp, Edgeware-road (near Cricklewood).

CONCUSSION AND PERCUSSION SHELLS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In page 96 of Captain Jervis's "Engines of War," he states that "Captain Moorsom, R.N. perfected concussion fuzes." Captain Moorsom's shell was and is a percussion shell. It was I who invented the concussion fuze as far back as 1842, and the select committee of artillery officers at Woolwich were so pleased with its performance that they officially reported that it was "simple, safe, and efficacious, being well adapted for horizontal fire with high velocities." I gave it the name of concussion fuze to distinguish it from all percussion shells of the spherical form, which latter I considered to be highly dangerous, as has since proved to be on more than one occasion. See former numbers of the MECHANICS' MAGAZINE.

I am, Gentlemen, yours obediently,
J. NORTON.

Rosherville, 24th Oct.

Extract from Colonel Beamish's letter to the Editor of the *United Service Magazine*, August 1859. "It is interesting to trace the progress of human invention, to observe the unaided struggles of genius, the frowns of fortune, the rebuffs of ignorant officials; 'the hope deferred,' the assumption, presumption, and jealousy of rival aspirants, until the name, and fame, and identity of the original are mystified and overlaid by modern pretenders, and the public are left in the pleasing predicament of not knowing 'which is which.'"

RULE TO FACILITATE THE USE OF LOGARITHMS FOR NUMBERS LESS THAN UNITY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Everybody who has worked much with logarithms knows that the raising of powers or extracting of roots of numbers below unity by their aid is attended with some inconvenience.

This arises from the fact that, in order to facilitate the use of the Tables, it is customary not to take the *real* logarithm of the number, but a certain substituted conventional one. For example, the real logarithm of 0.5 is — 0.301030, but as this number is not found in the tables, it is customary to take the log. of 5, and affix to it a minus index, marking it thus: $\bar{1}.698970$. This is an anomalous kind of expression, one part being positive and another part negative; and, therefore, it is scarcely to be wondered at that its management should cause trouble.

In multiplication or division by logarithms, the rules usually given, though somewhat confusing, are sufficient; but if involution or evolution with complicated exponents they fail; and it becomes necessary to resort to the true method of working, by finding the real logarithm instead of the substituted tabular one, i.e., taking the tabular logarithm of the *reciprocal* of the number, with a negative sign.

I venture, however, to propose a rule by which the substituted tabular numbers may be used, however complicated the exponent of the power or root may be:—

1. Express the exponent of the power or root in the form of a fraction, whose numerator and denominator are both whole numbers.

2. Having found the substituted logarithm from the tables, and given it a negative characteristic in the usual way, make this characteristic *positive*, by adding to it the denominator of the above fraction.

3. Work for the power or root in the usual way.

4. Then subtract from the characteristic the numerator of the before-mentioned fraction, which will bring it negative again, and the result is the substituted logarithm of the answer, which may be found at once by the tables.

This mode, though long in description, is very easy and simple in practice, as the following examples, scarcely practicable at all by the ordinary mode, will show:—

Required the value of $\left(\frac{5}{11}\right)^{\frac{1}{4}}$.

$$\frac{5}{11} = 0.4555.$$

$$\begin{array}{r} \text{Tabular Log.} = \bar{1}.6585411 \\ \text{Add denominator} = 11 \end{array}$$

$$\begin{array}{r} + 10.6585411 \\ \hline 5 \end{array}$$

$$11 \mid 53.2927055$$

$$\begin{array}{r} + 4.8417914 \\ \hline \text{Subtract numerator} + 5 \end{array}$$

$$\text{Tabular log.} = \bar{1}.8447914$$

$$= 0.69956 \text{ Answer.}$$

Required the value of $0.0000047381^{0.0682}$.

$$\begin{array}{r} \text{Here } 0.0682 = \frac{682}{10000} \end{array}$$

$$\begin{array}{r} \text{Tab. Log.} = \bar{6}.6756042 \\ \text{Add Denom.} + 10000 \end{array}$$

$$\begin{array}{r} + 9994.6756042 \\ \hline -0682 \end{array}$$

$$\begin{array}{r} + 681.6368762 \\ \hline \text{Subtract Numerator} + 682 \end{array}$$

$$\bar{1}.6368762$$

$$= 0.4333873 \text{ Answer.}$$

Required the value of $0.5^{2.53}$.

$$\begin{array}{r} \text{Here } 2.53 = \frac{253}{100} \end{array}$$

$$\begin{array}{r} \text{Tab. Log. } 0.5 = \bar{1}.698970 \\ \text{Add Denom.} + 100 \end{array}$$

$$\begin{array}{r} + 99.698970 \\ \hline 2.53 \end{array}$$

$$\begin{array}{r} + 252.238394 \\ \hline \text{Subtract Numerator} + 253 \end{array}$$

$$\bar{1}.238394$$

$$= 0.1731 \text{ Answer.}$$

"HOW BIG BEN SHOULD BE SUSPENDED."

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Will you oblige me by inserting in the next number of your Magazine a few words in reply to an article in the last number of the Magazine from Mr. Charles W. Lancaster on the subject, "How Big Ben should be Suspended." The method there mentioned by Mr. Lancaster originated from myself nearly two years since, and was at that time communicated to Mr. C. Mears previous to his casting the present Bell. It also appeared in the MECHANICS' MAGAZINE October 7, No. 41, in a letter from Mr. Loseby on Big Ben, and also in the Society of Arts Journal of the same date.

I am, Sir, Yours, &c.

THOMAS QUARRY.

THE GREAT EASTERN AND STEAM-SHIP ECONOMY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Permit me, in addressing to you a few observations on the formulae for steam-ship performances, to take the opportunity of advertising first, to an erratum in my last communication, by the omission of part of a sentence, thus rendering it somewhat obscure. I contended therein that in respect to the combination of speed and carrying power, "*the triumph of the Great Eastern was complete*," but the words in italics were omitted. I may add, that her performance was very satisfactory even as to absolute velocity, although it should be admitted that it never exceeded fourteen knots; because as your correspondent "*Atlantic*" observes, high speed merely was not the paramount object to be achieved, but economic speed, in relation to definite power, and in relation to such power and burthen; with the condition, however, that the absolute velocity should rank with the best steamers of the day. It was on this point of economic speed, in these its two relations, that my communication dwelt; pardon me, therefore, in saying, that your remark about my forgetting "that a very small (comparative) amount of engine power has been given to the Great Eastern," does not apply to my observations, although it certainly is pertinent in respect to absolute speed, and in regard to the incubrations of those newspaper reporters to whom you allude, and who, it is to be regretted, do not on like occasions hunt in couples, one as the literary and descriptive, and the other as the scientific observer, if the union of such talents in one person is not to be found. It does not apply in my case, because any variation in the magnitude of steam-power embarked in the Great Eastern ought, if within reasonable limits, to give nearly the same constants for dynamic performances.

Now, is the constant 692, as corrected by yourself, anything extraordinary, seeing that four ships of the Royal Navy exceed it! The formula which gives this constant has for its peculiar governing factor, the midship section of the vessel, and indicates the value of its *form*. The result, like that of absolute velocity, is satisfactory, and that is all that can be said. But in regard to the third point—the economic speed in relation to power and burthen—the result is successful in the highest degree, and much more I conceive than the constant 292 indicates, although there is not a vessel in the Royal Navy that approaches it. The appropriate formula in this respect giving the above constant is the usual one—

$$\text{Velocity}^3 \propto \text{Displacement}^{\frac{1}{2}}$$

Indicated Horse Power

Now, am I mistaken in supposing that this formula, although it may be appropriate for ships of the Royal Navy, does not apply properly to those of the steam mercantile class, and does not do justice to the performance of the Great Eastern in the aspect of commercial excellence, namely, speed in conjunction with great transport capabilities and economic employment of power? It appears to me that this formula does not relate purely to burthen, but mixes up with it the question of section; or rather it infers from the displacement a factitious midship section, instead of the real one, in order that tonnage as well as section should be represented. But surely these two elements should each have its distinctive formula, each excluding the influence of the other, if we would arrive at the merits of a ship in regard to its qualities separately and truly. The square of the cube root of the displacement excludes the influence of the great length in proportion to width for which the Great Eastern is remarkable. It is this, with her great size, and with good lines as a condition, which will give her such pre-eminence in a commercial point of view, and to a degree which no formula within my knowledge sufficiently indicates. Surely what is required is to take the simple displacement as the factor, and not any power thereof. Good lines will no doubt contribute to a good re-

sult determined after this manner, but that influence must be ascertained separately, by taking the midship section for the peculiar governing quantity. In this way it is seen that the Great Eastern presents no remarkable result arising out of her form; but at the same time it is seen that the result is so far satisfactory as to permit the other circumstances of her build to have full scope, for a dynamic performance of extraordinary commercial excellence.

May I be permitted to think that the appropriate formula for mercantile steam transport is a subject for the reconsideration of Mr. Atherton and the committee of Section G of the British Association.

I am, &c.

BENJ. CHEVERTON.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 53 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

AN APPEAL

TO THE SUBSCRIBERS AND READERS OF THE "MECHANICS' MAGAZINE."

Knows that we have the happiness to embrace among our subscribers and readers a goodly number of large-hearted and charitable persons, we take the liberty (being fully aware that it is a liberty) of bringing to their notice a case of peculiar hardship and distress which calls for something more than the relief which, as individuals, we have been able to afford it.

Early in 1857, a firm well known to the engineering world prosecuted a clerk of theirs for embezzlement, and got passed upon him a sentence of several years' imprisonment—a sentence which, as the judge himself said, was made extraordinarily heavy in proportion to the offence, on account of the prevalence of such offences just at that time. The wife of this man—a refined and excellent person—was left with no less than seven children to maintain, not one of whom was then contributing towards its own maintenance. Aided by two of her children she has, since her husband's conviction, laboured with the utmost industry, and to the full extent of her ability, to support her family, and has succeeded with the aid of a few friends in doing this until now, despite a long and dangerous illness. Her health is at last, however, sadly broken down, and unless assisted she will speedily be no longer able to keep her children about her, even should her life be prolonged.

A memorial, praying for a mitigation of the father's punishment, and setting forth in connection with this case other facts to which we need not here refer—which memorial was signed by the present Lord Mayor of London, the Rev. W. Cadman, M.A., of St. George's, Southwark, — Taylor, M.D., W. Cooper, Barrister-at-law, one of the Editors of this Magazine, and others—was lately presented to the Home Secretary, but for want of the signatures of the prosecutors was of no effect.

Believing that some of our readers might be willing, or even desirous, to contribute towards the relief and aid of this unhappy person and her family, we adopt this method of making the case known to them. Whatever they may be generous enough to send to ourselves (the Editors of the MECHANICS' MAGAZINE, 166 Fleet Street, London), shall be instantly transmitted to the objects of their benevolence, and duly acknowledged in our advertising columns or otherwise. We need hardly say that the smallest gift would help to gladden the mother's heart. We sincerely hope, therefore, we shall not fail to receive many immediate responses to our appeal.

Our Weekly Gossip.

SIR JOSEPH PAXTON proposes that the remains of George Stephenson should be removed to Westminster Abbey. He writes:—"It occurs to me that in honouring the son (Robert Stephenson), the father, who was pre-eminently the author of the locomotive system, ought not to be forgotten, but that his remains should be removed from the comparative obscurity in which they are now placed to Westminster Abbey, and that a suitable monument should be erected there in memory of father and son, to whom England and the world are so much indebted. The removal of the remains of the elder Stephenson was mentioned to me by some of his old associates not very long ago, although without any anticipation of the sad event which appears to make this a proper

occasion to bring the matter under public notice. If you, Sir, and the public agree with me in thinking such a step desirable, I am sure the authorities will gladly give their consent to the necessary arrangements; and the friends and admirers of the two Stephensons will not be wanting in their contributions. As a justification for putting myself forward in this matter, I beg to add that I was an intimate friend of the late George Stephenson, and that I also enjoyed the friendship of his son, whom, indeed, a short time before his fatal illness, I had arranged to join in a journey through Egypt next month."

The following letter on this subject has been received:—GENTLEMEN,—I quite agree with Sir Joseph Paxton, who has been honoured by Royal distinction for minor services, that the nation's gratitude should speak for itself, in the last tribute paid to the honoured memory of both those illustrious benefactors of their country, the Stephensons. Among the earliest and greatest works of the father George Stephenson, was the union of Liverpool with Manchester in less than one hour by railway and locomotive conveyance, thus largely contributing to make Liverpool the greatest port in the world, and Manchester the greatest town in the world for home and foreign cotton manufactures, besides leading to the formation of all the other railways in this and every other nation. The late Mr. Robert Stephenson stated in his address as President of the Institution of Civil Engineers in 1836 that railway engineers, railway surveyors and railway solicitors, divided between them two millions sterling; and no member of the engineering profession was more extensively and importantly engaged in the execution of these works than the late Robert Stephenson, who with his father, it is said, most deservedly realised nearly half-a-million of money. Among the results of the railway and locomotive system Mr. Robert Stephenson states in his address that the whole community in the United Kingdom were then saving (1836) in conveyance alone, forty millions sterling annually; and as this saving had been progressing gradually for twenty years previously, the aggregate amount saved may be computed to be at least two hundred millions sterling. The same patriotic and generous spirit which induced Sir Joseph Paxton to suggest a more appropriate resting-place for the remains of George Stephenson, the father, "as the author of the locomotive system," will no doubt induce the wealthy representatives of George and Robert Stephenson to rescue the remains of another illustrious railway and locomotive benefactor from still greater oblivion than Chesterfield, or the monument so generously and nobly intended at Newcastle-upon-Tyne—the only monument that was erected over the remains of the great man whom I now refer to being the most ordinary tombstone that could be afforded by his widow, scarcely visible and still less legible in the churchyard of Haughton village—not by removing his dishonoured remains to Westminster Abbey, though very much nearer than Chesterfield, but merely by substituting some humble tablet for the worn-out tombstone erected more than 58 years ago, over the grave. The inscription might be:—"This tablet was erected in 1859 by the representatives of the late George and Robert Stephenson, to the memory of Henry Cort, the founder of the British Iron Trade, and Tufel Cain of our country (See Times 29th July, 1859); he departed this life the 23rd May, 1800. Reader, bear in mind this, the humble individual who lies buried here, was robbed of all his property and patent rights by servants of the British Crown in 1763, who were the greatest robbers of the State ever known in English history; yet, without the inventions of this victim to State villany, no railway locomotive, steam engine, or electric telegraph, for manufacture or conveyance, could have been made available either in the old or new world: nor could the consumers of British iron have saved in the price of wrought iron alone, in the last sixty years, six hundred millions of money."

SUNNY.

We learn from the Paris correspondent of the Times that Admiral Paris, C.B., of Brest, has been doing good service in connection with the lifeboat system in France. A very useful pamphlet has just issued from the Paris press, entitled *Instructions sur la Manœuvre des Canots*. It originally appeared in English as *Instructions for the Management of Open Boats in a Heavy Surf and Broken Water, &c.*, and was published under the auspices of the Royal National Lifeboat Institution. The French translation has been very well done by Admiral Paris, and the pamphlet has been extensively circulated on the coasts of France. "I alluded some time since," says the writer just referred to, "to the lamentable want of lifeboats on the French coast, and the offer of the National Lifeboat Association to assist the French Government in this work of humanity. There is not so accurate a Wreck Register and Chart kept here as in

England, but it is known that hundreds of lives are every year lost from wrecked vessels on the coasts of France. France has an extent of sea-border from Dunkirk to Bayonne of nearly a thousand miles, yet, with the exception of one or two places, there is hardly a single efficient lifeboat on the whole of this extensive and dangerous line of coast, and, as for the mortar and rocket life-preserving apparatus, such things are very little known, perhaps never heard of. Saving human life is as noble a task as destroying it, even for an 'idea,' and the Emperor of the French could not carry out a better one than by ordering some practical and immediate steps to be taken to remedy the evil, and to provide efficient means for saving the lives of thousands of his subjects, and those of other countries, who are shipwrecked on the French coast, and who too frequently perish for the want of such means.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c. *None.*

BOILERS AND THEIR FURNACES, &c., 745.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 740, 759, 793, 794.

SHIPS AND BOATS, including their fittings, 732, 736, 738.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 743, 778, 786.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 733, 738, 764.

FIBROUS FABRICS, including machinery for treating fibres pulp, paper, &c., 739, 731, 771, 774, 776.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 741, 772.

LIGHTING, HEATING, AND VENTILATING, 737, 712, 719, 763, 772, 781, 782.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 736, 762, 790, 796.

METALS, including apparatus for their manufacture, 744, 752, 773, 777.

CHEMISTRY AND PHOTOGRAPHY. *None.*

ELECTRICAL APPARATUS, 755, 785.

WARFARE, 731, 757.

LETTER PRESS PRINTING &c. *None.*

MISCELLANEOUS, 733, 734, 735, 746, 747, 748, 750, 754, 760, 761, 763, 766, 767, 768, 769, 770, 773, 779, 780, 783, 788, 791, 795.

731. R. A. BROOMAN. "Improvements in fire-arms and ordnance, and in projectiles and apparatuses to be employed therewith." (A communication.) Dated March 22, 1859.

The patentee claims, 1, the construction of breech-loading arms described with reference to the drawings. 2. The use of a cartridge with a preliminary priming which is discharged by a pin or needle fitted in a hole of two different diameters. 3. The forming of a bullet to answer the purpose of an ordinary bullet and cartridge. 4. The application of the foregoing improvements in small arms to revolving fire-arms. 5. The construction of breech-loading cannons, described with reference to the drawings. 6. The construction of a non-recoil carriage for cannons, described with reference to the drawings. 7. The forming of projectiles for rifled small arms or cannons with wooden projecting plugs, either let partially into, or passing entirely through the projectile. 8. The construction of a rod with spring arms for cleaning out the bore and grooves of breech-loading cannon, all as described with reference to the drawings. *Patent completed.*

732. J. TRUSS. "An improved apparatus for indicating the speed of ships and other vessels." Dated March 22, 1859.

This consists of an apparatus to be fitted to a ship to show onboard the speed at which the ship is passing through the water. The inventor fits on the axis of a three-bladed screw, which is placed outside the vessel, a wheel inboard, which wheel gears into one or more wheels, and causes the last in a train to make a revolution when the vessel is progressing at any one knot an hour, which revolution is shown upon an indicating dial. *Patent completed.*

733. C. A. WATKINS. "Improvements in the manufacture of brushes." Dated March 22, 1859.

The patentee claims, 1, a method of securing hair in circular and oval brushes by means of certain metal

bindings. 2. The manufacture of socket brushes and sockets for brushes with a binding formed of wire rods or strips of metal, such binding being employed as the socket itself or to form only part of the socket. 3. The holding of the binding for brushes together while being formed, and the binding after being formed, to the block or cap by strips of metal. 4. The use of a pin for securing the block of socket brushes to the handle. 5. The securing of wire bound brushes generally by soldering the wires together after the brushes are made—all as described with reference to the drawings. *Patent completed.*

734. J. MACINTOSH AND G. RUDELS. "Improvements in tents and such like coverings for shelter against the weather." Dated March 22, 1859.

This invention has been described and illustrated in the MECHANICS' MAGAZINE. See pages 291 and 220, Vol. 1 (New Series). *Patent completed.*

735. S. ORAM. "Improvements in pipes or tubes for generating and superheating steam." Dated March 23, 1859.

The improved pipes are made of spiral, corrugated, undulated, or indented forms to give increased heating surface. *Patent completed.*

736. W. ADAMSON. "Improvements in apparatus for propelling vessels." Dated March 23, 1859.

This is applicable to vessels of light draught. The patentee places on the under side of the vessel a flap which turns at one of its ends on an axis parallel with the keel. This flap works water tight within a chamber of a suitable form to permit it to make a partial revolution on its axis. The chamber is open at its after end, and in the sides of the chamber there are valves which alternately open and permit water to flow into the chamber when the flap is moved away from the side in which they are situated, and close when the flap is moved towards them, the water being thus forced out at the open end of the chamber, by which means the vessel is propelled forward. *Patent completed.*

737. S. CLARKE. "Improvements in the manufacture of candles." Dated March 23, 1859.

This consists in manufacturing candles with their lower ends composed of plaster of Paris or other cement, which, in addition to extending the lengths of the candles, also sustains the wicks whilst the lower portions of the candles are being consumed. *Patent abandoned.*

738. W. MIDDLESHIP. "Improvements in propelling vessels." Dated March 23, 1859.

Here the screw is to be made hollow, or open at the centre, so that its interior space may communicate with the interior of a hollow shaft on which the screw is mounted. Water is to be admitted to the central hollow shaft, and allowed to flow to the ends of the arms, blades, or plates of which the screw is composed. The water will be discharged obliquely at the periphery of the screw, and if desired it may be arranged to deliver the water from suitable openings at either side of the blades. The reactionary force of the effluent water rushing from the openings in the blades will cause the screw to rotate. *Patent completed.*

739. J. EVANS. "Improvements in the manufacture of paper." Dated March 23, 1859.

Here the paper is furnished by bringing it into contact with one or more polished rolls, driven rapidly as compared with the surface speed of the paper, the paper being supported by other hard and polished rolls. *Patent completed.*

740. B. BROWNE. "A new method of working or operating switches and signals on railways by improved apparatus for such purpose." (A communication.) Dated March 23, 1859.

This consists in working switches and disc signals by causing the flanges of the running wheels of the carriages and locos connected to the engine to actuate mechanism fixed at certain parts of a line of railway. The mechanism consists of a hydro-pneumatic swing table, connected with which are pumps in which oil is placed. An important feature in this invention consists in employing oils of a non-siccative character, or not capable of congealing in cold weather. *Patent completed.*

741. J. V. HIBLAKE. "Improved apparatus for pressing or moulding artificial or patent fuel, fire-bricks, and similar articles." Dated March 23, 1859.

This consists of certain new mechanical arrangements constituting an apparatus in which percussion force is to be employed for effecting compression of the materials to be moulded. *Patent abandoned.*

742. G. NEAL. "Certain improvements in apparatus or fittings connected with the burning of gas for regulating and economizing its consumption." Dated March 23, 1859.

In this description of regulator the chamber or cavity containing the principle of regulation forms the base of the part that extends up, surrounding the base of the burner. This cavity the inventor fills with

sponge or other like porous homogeneous matter, in a bulk, or in separate layers, so arranged that by a perforated plate, or by wire gauze discs suitably strengthened, he is enabled to compress such porous matter so as to regulate or allow the gas to penetrate through it at such a rate that when lit it shall be enabled to commingle with and consume a due proportion of atmospheric air to produce silent and perfect combustion in the burning of gas, and consequent purity and brilliancy of light. *Patent completed.*

743. W. DELANY. "Improvements in ploughs for tilling land." Dated March 23, 1859.

This consists in the use of a number of wheels fixed upon stationary horizontal axles carried in a rectangular frame. A cam groove is formed in the periphery of each wheel, which groove is in a plane at right angles to the axle, excepting at one part where it is made to diverge slightly out of its course, and to return to it again. These wheels are each enclosed by a pair of discs formed with flanges at their peripheries, and rotating loosely upon the axles, the flanges surrounding and enclosing the wheels. These discs carry at their peripheries a series of cutters or knife-edged plates which radiate from the axles, and revolve with the disc so as to cut the surface of the soil into strips, and then to turn such strips over after the manner of the ordinary mould board of the plough. *Patent abandoned.*

744. J. H. JOHNSON. "Improvements in machinery or apparatus for the manufacture of sheet tin." (A communication.) Dated March 23, 1859.

This consists in attaching the vessels into which the melted tin is poured to endless bands or chains which have a continuous travelling motion imparted to them. Elastic bars are so arranged as to moderate the pressure of the vessels against the spreading plate or surface during their passage over or along such surface. *Patent completed.*

745. P. P. BOLL AND H. REGER. "Improvements in steam boiler and other furnaces." (A communication.) Dated March 23, 1859.

This consists in constructing furnaces with two or more fire-places in combination with suitable flues, so arranged that the gases distilled from the fuel fed upon the fire bars of one fire-place shall be caused after traversing the furnace to enter beneath the fire-bars of another fire-place and pass up through the hot fuel upon them, being thus effectually consumed. *Patent completed.*

746. F. TILLET. "Improvements in machinery for cutting splints for matches." Dated March 23, 1859.

This consists in combining a set of reciprocating lances or cutters (for grooving the block to be cut into splints) with a knife or cutter for slicing off the grooved portions, so that the cut of the slicing knife shall take place at right angles, or nearly so, to the cut of the grooving instruments. *Patent completed.*

747. W. AND J. GARFORTH. "A certain improvement in metallic pistons." Dated March 24, 1859.

This consists of an outer ring or rings of ordinary construction which are to be expanded against the cylinder by an internal V-ring made in sections, each of which sections being provided with a small piston or pistons, one end of which acts upon the ring, and the other receives the direct pressure of steam which is supplied and conveyed to an angular space in the interior of the piston by a steam pipe which rises and descends through a stuffing box in the cylinder cover with the action of the piston. *Patent completed.*

748. W. E. WILEY. "Improvements in the manufacture of boxes or cases used for holding needles, pens, matches, pencils, and for other like purposes." Dated March 24, 1859.

This invention embraces various modifications, and is not fully described apart from the drawings. *Patent completed.*

749. W. E. WILEY. "New or improved instruments to be used in burning and supporting candles." Dated March 24, 1859.

This consists principally of a cap, or a tube terminated by a cap, which cap or tube is placed upon the candle while burning. The wick of the candle protrudes through a hole in the summit of the cap or tube, and the said cap or tube, resting on the top of the candle, descends as the candle burns. *Patent abandoned.*

750. F. E. SHARP. "Improvements in machinery for corking bottles." Dated March 24, 1859.

This consists in the use of a table moving on a centre axis, in connection with which are certain wheels and levers, which upon being actuated either by steam or other power effects the working of the bottles. *Patent completed.*

751. E. S. TERBUTT. "Improvements in

manufacture of elastic fabrics." Dated March 24, 1859.

The inventor cements in the ordinary way the inner surfaces of the fabrics which are to be united to form the compound elastic fabric, and inserts between them bands or tapes of india-rubber, the tapes being at tension at the time of the joining of the fabrics in order to produce the puckering or corrugations. *Patent abandoned.*

752. C. SANDERSON. "Improvements in preparing, tempering, and covering or coating thin strips or sheets of steel." Dated March 24, 1859.

One of these improvements consists in hardening the strip or sheet of steel when in the full or normal size, as it comes from the cold rolls, and before it is cut up into the narrow strips which constitute crinoline steel. The strip or sheet is coiled round so that a small space is left between each coil. This is effected by coiling along with the strip of steel a piece of wire of a thickness corresponding to the distance required between the coil of the sheet. When the sheet of steel is coiled in this manner the oil in which it will be plunged to harden it will circulate over the whole surface of the strip. After removal from the muffle in which it has been treated a spindle is passed through the centre of the coil, and the strip of steel being removed therefrom is gradually passed between a pair of metal discs which are kept at a red heat. *Patent completed.*

753. W. CLARK. "A machine for separating oats from their husks or chaff." (A communication.) Dated March 24, 1859.

This invention is not described apart from the drawings. *Patent completed.*

754. H. RIGBY. "Improvements in machinery or apparatus for obtaining motive power, applicable to hoists, and all other purposes to which motive power can be applied." Dated March 25, 1859.

The patentee employs an upper reservoir of water, and by a regulating valve allows the water to fall upon the buckets of a water-wheel or turbine, the water being delivered into a similar reservoir below. The water-wheel or turbine gives motion to a series of hydraulic pumps for forcing the water into one or more hydraulic rams, to each of which a larger pump bucket is attached, working in a suitable barrel, the bottom of which is placed in the lower reservoir. As the turbine turns from the supply of water, and gives motion to the series of pumps, the ram or rams rise and raise the larger bucket or buckets, the effect of which is to raise the surplus water from the lower reservoir to the upper. *Patent completed.*

755. C. COWPER. "Improvements in telegraphic cables." (A communication.) Dated March 25, 1859.

Here copper wire is first covered with a coating of gutta-percha, &c., and then with a mixture composed of caoutchouc, gum lac, tar, and cork reduced to powder, in such proportions that the cable shall be but slightly heavier than the water. *Patent abandoned.*

756. R. BAKER. "Improvements in chronometers, watches, and other time-keepers." Dated March 25, 1859.

This consists in constructing the escapement of chronometers, watches, &c., with a balanced detent lever carrying a pin which enters a groove in a piece or block carried by the balance, except at the point where the impulse is to be given. *Patent completed.*

757. J. H. JOHNSON. "Improvements in fire-arms." (A communication.) Dated March 25, 1859.

This relates more particularly to that class of self-primers wherein the magazine is contained in the hammer of the lock. It is proposed to combine suitable mechanical devices with the slide which pushes forward the individual primers (which are of the flat or wafer kind) into the striking part of the hammer, by which combination the slide can be kept rigidly in position over the mouth of the magazine chamber, so as to intercept all communication with the latter. *Patent completed.*

758. W. E. NEWTON. "Improvements in ovens for baking bread and other substances." (A communication.) Dated March 25, 1859.

This relates to an arrangement of parts whereby the oven is rendered automatic, and consists in a system of screws and endless chains in combination with a system of permanent ways or tracks leading from end to end of the interior, and through the doorways of a horizontal oven. The invention is not fully described apart from the drawings. *Patent completed.*

759. C. HILL. "Improvements in the permanent way of railways." Dated March 25, 1859.

When supporting the rails by side bearing plates having flanges on one or both sides, the inventor forms the rail with a web or keel which projects downwards below the bearing plates, strengthening the rail itself, and preventing it and the bearing plates

from moving sideways; the lower end of this web or keel may be formed with a flange or rest projecting on each of its sides. There are various modifications included. *Patent abandoned.*

760. H. HUMPHREYS, Sen. "An improvement in unhairing hides and skins, and in the manufacture of leather." Dated March 25, 1859.

This consists in the application of the ashes of spent tanners' bark in the unhairing process. The spent tanners' bark is burnt to an ash, the ash combined with water, and is then used. *Patent abandoned.*

761. G. HASLETT. "Improvements in the manufacture of small metallic chains." (A communication.) Dated March 26, 1859.

This relates to the construction of a chain composed of domed or cup-shaped links, the several operations being performed by certain novel mechanical devices. The invention is not described apart from the drawings. *Patent completed.*

762. W. REDGRAVE. "An improved pillow travelling cap." Dated March 26, 1859.

The inventor describes a tube of air-tight material. *Patent abandoned.*

763. E. STRANE. "An improved means or apparatus for preventing candles dropping or guttering." Dated March 26, 1859.

This consists in a protecting hood, cap, or cover, to fit over the top of the candle, descending as the candle burns away. *Patent completed.*

764. S. DREYFOUS, G. RICHES, and E. CORNIER. "Improvements in preserving eggs." Dated March 26, 1859.

This consists in introducing the eggs into boxes moulded of plaster of Paris, and hermetically sealing the boxes, the eggs being wrapped in paper and surrounded with charcoal powder. *Patent abandoned.*

765. M. FIRTH. "Improvements in machinery for grinding saws and flat plates of steel." (A communication.) Dated March 26, 1859.

Here the patentee arranges beneath a grinding stone an adjustable table, supported at one end by a short shaft forming a hinge, which rests on a casting or pan. To this casting or pan set screws are fixed for regulating the table that it may grind the saws thinner on the back if required. The other end of the table rests on a screw attached to a wheel, by which the table can be raised to the face of the grinding stone, or withdrawn from it at pleasure. On top of the said table he places a carriage on which the saw to be ground is placed, and is made to travel backwards and forwards in a direction transverse to the axis of the stone, or nearly so. To prevent the saw from coming off the carriage while in the process of grinding he affixes a plate of metal at one end of the carriage, of nearly the same thickness as the saw to be ground. One end of the saw coming against the said plate prevents it from coming off the carriage while grinding. He also places a cover over the saw to prevent it from spinning off the carriage. The table and carriage rest in a wooden frame, to which are attached two standards for supporting the brackets in which the shaft supporting the grinding stone revolves. *Patent completed.*

766. G. NAYLOR. "An apparatus for measuring and indicating the distance passed over or travelled by the same." Dated March 26, 1859.

This consists in the combination of a graduated "motive or running wheel," a "toothed wheel moving in trundle gear," a dial-plate, and a hand or pointer. *Patent abandoned.*

767. J. C. EVANS and P. SOAMES. "Improvements in apparatus for superheating steam." Dated March 26, 1859.

This consists, 1, in the use of a set of superheating pipes in front of the tube-plate. 2 In the employment of a superheating chamber, heated by a separate fire. 3. In the use of superheated pipes, heated by a highly heated fluid, or by molten metal. 4. In the general arrangement of apparatus, shown in drawings. *Patent completed.*

768. M. A. MUIR and J. MCILWHAM. "Improvements in moulding or shaping metals." Dated March 26, 1859.

This relates to a system of mechanically moulding various moderately-sized articles in metal, but in particular railway chairs. The mechanical arrangements consist essentially of two separate divisions, viz., that relating to the ramming of the moulding sand upon the pattern, and that comprising the removal of the pattern from the moulded sand, or the "drawing" of the pattern. We cannot quote the details of the invention here at sufficient length for an intelligible abstract. *Patent completed.*

769. E. DOWLING. "Improvements in weights." Dated March 26, 1859.

Here the inventor forms glass weights of any suitable shape, but for the large ones he prefers them circular with a double bulge and flat at the bottom,

the larger bulge serving as the base, and the smaller one to take hold of. He forms a hole through the body of the glass from top to bottom, such hole being largest at the ends and small in the middle. Thus a cylindrical piece of lead or other soft metal may be inserted and pressure applied above and below, which will fix the lead or soft metal firmly in the glass. *Patent abandoned.*

770. B. and C. L. SMITH. "Improvements in the preparation of certain colouring matter, applicable for dyeing and printing." Dated March 26, 1859.

This consists in precipitating the colouring matter from ordinary archil liquors of commerce, so as to obtain from them the colouring matter in a concentrated or solid form. *Patent completed.*

771. J. BUCKLEY, O. GREENHALGH, and R. HUTCHINSON. "Improvements in machinery or apparatus for printing woven fabrics." Dated March 26, 1859.

This consists of an apparatus for printing both sides of a fabric at once. It is not described apart from the drawings. *Patent completed.*

772. C. J. RICHARDSON. "Improvements in apparatus to be applied to chimneys or flues of buildings, for preventing down draught or return smoke, for their insuring upward ventilation, and for reducing the quantity of smoke or the blacks from the smoke passing into the atmosphere." Dated March 26, 1859.

This consists in a contrivance for the prevention of down draught, called the "wind cap," in a contrivance for securing ventilation called the "iron stack flue," and in a contrivance for reducing the quantity of dense smoke or blacks passing into the atmosphere called the "rain vase." We cannot devote space to the details of the invention. *Patent completed.*

773. C. F. VASSEROT. "An improved diving apparatus." (A communication.) Dated March 26, 1859.

This consists of a garment formed of metallic framework, the joints of which are covered with a water-proof coating. By means of this garment a body sunk at the bottom of the sea may be visited, and chains fixed to for raising it. Each chain enters an iron tube which passes at different inclinations through a large cylinder of sheet iron, and the upper part of each tube is furnished with a check for holding the chain when it is drawn up. This cylinder is connected by caoutchouc pipes with an air pump, and has valves for the admission and effluxion of water. *Patent abandoned.*

774. J. BUCKINGHAM. "Improvements in machinery or apparatus employed in drawing fibrous substances." Dated March 26, 1859.

This consists in the application to the surface of the leather coverings of covered rollers of "a varnish or solution of gutta-percha, or other similar gum, non-soluble in oil, dissolved in any suitable solvent." *Patent completed.*

775. A. V. NEWTON. "An improved construction of furnace for reheating steel, preparatory to the hardening, tempering, or annealing process." (A communication.) Dated March 26, 1859.

This consists in so arranging the furnace as to cause the flame and heat to act upon a closed oven or chamber in which the metal to be operated upon is placed, so as to distribute the heat under, above, and in the back of the oven or chamber, and to communicate a powerful and steady heat to the interior of the oven or chambers, while such interior and its contents have no communication with the flame or gases of combustion, and as little as possible with the external atmosphere. *Patent abandoned.*

776. A. TURNER. "Improvements in the manufacture of elastic fabrics." Dated March 26, 1859.

This consists in the use of threads or yarns composed of wool in combination with some other fibrous material, such as silk, cotton, flax, &c. These compound threads are chiefly intended to be used as warp threads. Strands of india-rubber may be combined with the above. *Patent abandoned.*

777. A. V. NEWTON. "Improved apparatus for retaining the oil or other fluid used for annealing, tempering, and hardening steel at any equal low temperature." (A communication.) Dated March 26, 1859.

The apparatus here employed consists of two large iron cylindrical tanks placed side by side at a short distance from each other in a timber framing. The tanks are connected by a pipe near the bottom to allow the fluid to run freely from one vessel to the other. Within each tank is a worm or coil of metal pipe through which water circulates to keep the oil cool. A space is left in the centre of the coil in one of the tanks for a well in which the springs or metal may be plunged and withdrawn without interfering with the coils. These tanks have moveable covers perforated with small holes, and the cover of the immersion tank has a circular opening at the centre, large enough to

admit the springs or pieces of steel with facility. The small holes in the cover act as strainers for the oil from the springs, &c., placed upon them. Over and upon the central part of the other tank there is a metallic cylindrical chamber which contains a central tube and a series of horizontal perforated discs. In connection with this chamber is a pumping apparatus whereby the heated oil is drawn from the immersion tank through a suitable pipe and delivered into the perforated discs of the upper chamber from which it descends in a shower, and is cooled by currents of air. The cooled oil runs through the perforated cover of the tank below into the said tank and from thence into the immersion tank. *Patent abandoned.*

778. T. CARR. "Improvements in machinery for disintegrating artificial manures, and various other substances." Dated March 29, 1859.

This consists of a series of circular cages, arranged on an axis concentrically, the outer periphery of each cage being composed of bars having open spaces between them. The material is placed in the central cage, and it is by centrifugal force thrown through the bars of the several cages. The cages move in contrary directions. *Patent completed.*

779. C. L. ROBERTS. "Improvements in cigars." Dated March 29, 1859.

This consists in enclosing within the ends of cigars mouth-pieces of glass, earthenware, wood, &c., having inner tubes or linings of straw, and so placed as to admit of one end being held within the mouth whilst the other is embedded in the cigar. *Patent completed.*

780. W. MOSSMAN. "Improvements in machinery applied to embossing or cutting presses, for the better and more expeditious manner of manufacturing ornamental, cut out and embossed work in paper, leather, parchment, cloth, foil and other materials." Dated March 29, 1859.

This consists in affixing a plate or block to the dab of the embossing or cutting press, or placing between the dab and the die a plate or block of metal adapted so as to press or bear equally on all the cutting edges of the die or dies. Also using in the manufacture of such ornamental work thin plates of metal, especially zinc, for the cutting edges of the dies to press against; also for the sliding framework and moveable point or points, to the lid or cover for the paper or other substances when cut remaining in the die until embossed. *Patent completed.*

781. J. W. KELLY. "Improvements in gas-burners." Dated March 29, 1859.

This consists, 1, in the application of a small cylindrical tube or ring of brass or other metal to the outside or top of the burner, whereby a more complete combustion of the gas is obtained. 2. In making a small number of apertures immediately above or on the burner side of the cock, which apertures are to be of various sizes, and in covering or enclosing these apertures in a small bell-shaped or other form of chamber, at the top of which is to be inserted a burner of larger apertures than any of those enclosed beneath. By this means, and with the aid of an external index or dial, the key of the cock may be turned so as to lead to the gas through any of the apertures mentioned, and thus let pass to the burner a quantity of gas corresponding exactly to that which would be issued by any one of the burners now in use. *Patent completed.*

782. E. DE CARANZA. "A new system of gas lighting through new apparatuses and matters richer in gas than pit-coal." Dated March 29, 1859.

Here the inventor obtains gas from boghead or compile clay, greasy sawdust obtained from wood that has been used in refining or cleansing fatty matters, pit-coal, and the fatty residues left in the extraction of schistic oils. The invention comprises an arrangement of cylinders, retorts, and furnaces, specially applicable for use in private establishments. *Patent abandoned.*

783. E. N. NORMINTON. "The cleansing and re-manufacturing of old used dirty railway grease for the manufacturing of new railway grease, for the cleansing and re-manufacturing of old used cotton waste, tow, or any other textile fabric, and for the purifying of oils, or any fatty matter." Dated March 29, 1859.

This consists in the combination of carbonate of soda, sulphate of soda, or sulphuric acid, with palm oil, or other fatty matter for the manufacture of railway grease. It also comprises various operations for effecting the objects indicated in the title. *Patent abandoned.*

784. T. W. MERRINS. "The production of a motive power and of a projectile and explosive force to be used in instruments of war." Dated March 29, 1859.

The object here is the evolution of gases in the

same, or in separate vessels, by electricity, or by other means, and the invention consists in their introduction into a cylinder in a mixed or separate state, to be there combined by an electric spark, or by other means. The invention is applicable to various purposes. Provisional protection was not granted for this invention.

785. R. SEARLE. "Improvements in apparatus used for transmitting signals by electricity for telegraphic purposes, and in the construction of telegraphic cables." Dated March 29, 1859.

The patentee claims, 1, the mode of manufacturing telegraphic cables with a core centre or foundation formed of bamboo or rattan canes spliced together so as to form a support of the required length. 2. Placing the wire band or ribbon in a spiral form round or upon the core or support, by which means the patentee removes the tension or strain of the cable from the conducting medium. 3. Increasing the surface of the metallic conducting medium by forming it into three bands or ribbons, or grooved or corrugated wires. *Patent completed.*

786. I. SPIGHT. "Improvements in horse-hoes." Dated March 29, 1859.

Here the hoes are attached to levers connected with a revolving shaft near the front of the machine. This revolving shaft works in bearings in a slide frame, and is moved by turning a handle attached to a shaft working a rack or worm thread, by means of which all the hoes work on the same level. One end of each of the levers, to which the hoes or hoe shanks are attached, being fixed to this revolving shaft by sockets or otherwise, instead of hanging loosely as heretofore, the hoes will all cut level, and not be liable to clip on one side. The depth to which the hoes penetrate the ground is regulated by the height of the revolving shaft in the slide frame. At the top of each of the hoe shanks is a socket which slides upon the lever connected with the revolving shaft, and which may be fixed in any position required for different kinds of corn or roots by set screws, clasps, or otherwise. *Patent completed.*

787. T. TAYLOR. "Improved means of giving increased strength to paper." Dated March 29, 1859.

This consists in soaking paper when dry in a concentrated neutral or nearly neutral solution of chloride of zinc, either at the natural temperature of the air, or moderately heated, and afterwards thoroughly washing the paper in water. *Patent completed.*

788. H. P. BURR. "Improvements in apparatus for preparing and preserving timber." Dated March 29, 1859.

This relates to apparatus for impregnating railway sleepers and other timber with creosote or other preservative liquids or solutions, which apparatus may also be used for impregnating timber with liquids or solutions for clearing the wood, or for rendering it incombustible. *Patent completed.*

789. H. MOSS and T. WEST. "A machine for the cutting of leather for every purpose, and cutting cloths, linen, and other fabrics and materials." Dated March 29, 1859.

This relates to regulating the feed, and consists in the use of a self-acting table, on which, by means of a cam motion, is worked a knife, constructed so as to cut a square edge; the machine may be worked with or without a self-acting feed. The knife is so constructed, from its being larger at the top than at the bottom, that when applied without the self-acting feed it may be discharged from the top, so that it gives a facility for cutting some six or seven shapes before it requires emptying; it is also so constructed that when the self-acting feed is applied by the application of springs, it leaves the material which is being cut quite clear of the knife or stamp. *Patent completed.*

790. W. BROWN. "Improvements in manufacturing clog soles, and in the machinery employed therein." Dated March 30, 1859.

This consists in the use of certain cutters having a rotary or reciprocating motion given to them by steam, or other power. *Patent completed.*

791. J. H. LINSLEY. "Certain improvements in binding or covering books." Dated March 30, 1859.

This consists in fixing to the back of the leaves of the book a strong cloth or leather hinge, as is usually employed, which is secured to the cover by plates of metal, one of which is fixed to each cover; two other metal plates clip or confine the loose sides or flaps of the hinge between them, so that a new set of leaves may be securely fixed without injury to the book or covers. *Patent abandoned.*

792. J. W. HADWEN. "A new art or manufacture for converting certain kinds of silk waste into yarns or threads." Dated March 30, 1859.

The patentee claims the combination of the several processes of dressing, drawing, doubling, roving, and spinning applied in the manner set forth to the

manufacture of yarns or threads from uncut and long fibred soft silk waste, and also the combination of the several processes of drawing, doubling, weaving, and spinning, applied as described to the manufacture of yarns or threads from uncut and long fibred soft silk, after the said waste has been dressed, combed out, cleared, &c., &c. *Patent completed.*

793. W. V. EDWARDS. "Improvements in the construction of ways and apparatus to facilitate the conveyance of mails, goods, and passengers." Dated March 30, 1859.

Here a tunnel or enclosed passage is constructed between distant places. At the lower part of such tunnel two parallel trams or rails are formed in longitudinal grooves or recesses. Arrangements are made for a train of carriages to be brought to rest by means of valves which are caused to descend and close a given section or length of the tunnel, and passages are opened to admit air into such closed sections, in order that there may be no pressure of air acting on the carriages in one direction, whilst the tunnel is exhausted in advance of the carriages. A piston is applied in advance of or behind the train, and the tunnel is kept exhausted in advance of the carriages when they are required to be in motion. *Patent abandoned.*

794. G. T. BOUSFIELD. "Improvements in preventing explosions in steam boilers." (A communication.) Dated March 30, 1859.

This consists in the application to various kinds of engines, of an apparatus for stopping entirely or partially the flow of steam, &c., to the engine when the pressure becomes too high, and by this means to stop or retard the engine. *Patent abandoned.*

795. T. D. SHIPMAN. "Improvements in apparatus for stamping and printing." (Partly a communication.) Dated March 30, 1859.

Here the printing surface is fixed in a suitable frame, which is affixed to and slides with an upright bar or rod, which moves in suitable guides. The rod or bar is attached to one end of a lever, and the other end of the lever is constantly drawn downwards by a suitable spring, so as to raise the printing surface when allowed to do so. An inking roller is carried by the forked end of a lever which has its axis or fulcrum above the lever before mentioned. The other or back end of the forked lever is constantly drawn on by a suitable spring, so as to cause the inking roller to pass under the printing surface. The back end of the forked lever is attached by a link or connecting rod to the fore part of the lever, which acts on the printing surface, by which the movement of the forked lever is caused to depend on the movement of the other lever; by this means at each movement an impression is produced. There are also arrangements in connection with the inking process. Under the printing surface there is an elastic bed of vulcanized india-rubber. *Patent completed.*

796. H. JEFFERIES. "Improvements in castors for furniture." Dated March 30, 1859.

Here, in making a castor of that description where a sphere is used as the roller, the frame or body of the castor is made of one piece of glass, china or earthenware, with a recess at its under side to receive the spherical roller. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Aug. 30, 1859.

1973. T. Eastman. Improvements in screw propellers. (A communication.)

Dated Oct. 1, 1859.

2225. S. Ward. An apparatus to be used in the hardening of saws and steel plates generally.

2227. C. Brown. Improvements in inkstands and date indicator.

Dated Oct. 4, 1859.

2240. J. Rawlings. An improved construction of boot-tree.

Dated Oct. 6, 1859.

2271. G. A. Smith. Improvements in shot and shells, and other projectiles.

2278. W. Hopkins. A new or improved steam engine.

2276. G. Freeman and J. Royle. Improvements in looms.

2277. W. Macfarlane. Improvements in machinery or apparatus for drawing off or discharging liquids, and in fountains, baths, and similar receptacles for liquids.

2279. W. Benson. Improvements in projectiles for muzzle-loading rifled ordnance.

2281. W. Barron. Improvements in boilers applicable to heating and steam generating purposes.

2283. W. E. Newton. Improvements in the construction and manufacture of casks, barrels, and such like vessels, and in the machinery or apparatus to be employed for such manufacture. (A communication.)

Dated Oct. 7, 1859.

2935. G. L. Lee. Improvements in producing printing surfaces.

2937. G. P. Dodge. Improvements in apparatus for preserving life, applicable to garments. (A communication.)

2980. D. McCallum. Improvements in electric telegraphs.

Dated Oct. 8, 1859.

2291. W. Irlam. Improvements in the construction of railway turntables and cranes.

2293. J. Brough. An improved waterproof dress for protecting and saving life at sea or in any other situations where a waterproof dress may be required, as also in the apparatus to be attached to or used with the same, for assisting the wearer to hoist or make signals, by night or by day, and to inflate, propel, and guide or direct himself as desired, the waterproofing principle of which being also applicable to other useful purposes.

2295. J. Childs. Improvements in the manufacture of artificial gums.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Oct. 25, 1859.)

1411. W. Donbavand and D. Crichton. Looms.
1421. O. Maggs. Washing machines.
1430. C. N. Kottula. Purifying the Thames.
1433. J. Cowan. Soap.
1452. H. F. Smith. Driving straps.
1457. T. Orrell, jun. Mules for spinning.
1459. E. T. Hughes. Treating fatty substances. (A communication.)

1465. A. V. Newton. Assorting substances of different specific gravities. (A communication.)

1468. J. Cox. Cutting rags.

1469. A. Jeffery. Projectiles.

1471. R. Harper, B. Stokes, and T. Walker. Bonnet wreaths and feathers.

1473. G. J. Parker. Giving alarm of fire.

1475. P. F. Acerts. Lubricating.

1481. C. L. J. Dierckx. Coining.

1485. W. Rowan. Generating steam.

1490. E. Oliver. Medicine for rheumatism, &c.

1506. J. Apperly and W. Clissold. Wheels.

1507. M. A. F. Menmons. Bolts and rivets. (A communication.)

1542. R. Dick. Addressing cards, &c.

1539. W. E. Newton. Steam engines. (A communication.)

1550. T. Bell. Manure.

1573. S. Fisher. Ordnance and projectiles.

1604. C. Hagan. Curing smoky chimneys.

1652. J. Luis. Railway car seats and armchairs. (A communication.)

2163. H. Winter. Lifting and weighing.

2122. T. Elliott. Lubricators.

2133. R. A. Brooman. Elevators or lifts. (A communication.)

2170. T. B. Daft. Coating conductors.

2172. J. Todd. Screw propellers.

2190. W. Collins. Hydrants.

2202. C. Stevens. Steam-dredging boat. (A communication.)

2217. B. Atkinson. Railway brakes.

2267. J. Macintosh. Flexible tubes.

2269. J. Macintosh. Coating conductors for telegraphs.

2277. W. Macfarlane. Drawing off liquids.

2283. W. E. Newton. Casks, &c. (A communication.)

2331. T. Twells. Embroidering.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Oct. 19, 1859.

904. J. M. J. and E. Johnson.
1002. J. Napier.
1005. D. Auld.
1007. F. Lewthwaite and G. Ambler.
1010. T. S. Truss.

1018. J. Angus.
1025. J. Marshall.
1030. J. Higgin.
1044. W. Mackenzie.
1048. R. A. Brooman.
1055. H. R. Fanshawe.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

2442. R. H. Collyer.
2402. H. Deacon.
2474. G. Thomson.

2476. W. E. Newton.
2494. G. Ermen.
2504. L. A. Mangin.

PATENTS ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

450. G. Heyes.
401. J. Gilbert and S. Nyo.
655. R. B. Cousens.
725. J. F. Belleville.

LIST OF SPECIFICATIONS, &c.,

Published during the week ending Oct. 21, 1859.

No.	Pr.	No.	Pr.	No.	Pr.	No.	Pr.	No.	Pr.	No.	Pr.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF DESIGNS FOR ARTICLES OF UTILITY REGISTERED.

Date of Registration.	No. in Register.	Names and Addresses.	Subjects of Design.
Oct. 3.	4202	Williams & Bate, Birmingham.	Case.
" 5.	4203	T. Ridge, Hackney.	Upper for boots.
" 6.	4204	Lovell & Co. Schoolbred, Wolverhampton.	Coal scap.

REMARKS.—All metals are in rather a depressed state, and scarce any business is being done. A feeling of much uncertainty prevails as to what effect political complications are to have on trade.

LAWRIE AND HAGGER, Metal Brokers

31 Lombard-street, E.C.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

BATTERY, *Limp's Fort, near Portsmouth*.—Parties desiring to tender are required to attend at the Royal Engineer Office, Portsmouth, 31st October, at 10 o'clock, to appoint a surveyor to take out the quantities in conjunction with the Government surveyor. Each party is required to pay two guineas for the quantities.

RAILWAY BUILDINGS, *Scotland*.—For the Maybole and Girvan Railway. For the erection of timber station-house at Maybole; timber booking office for Crosshill; cottage for level-crossing lodge at Kilkerran; stone-built goods shed for Girvan; timber station-house for Girvan; and tank, engine, and carriage shed of same material. Plans and specifications, secretary's office in Girvan. Further information from Mr. J. Miller, 25 Northumberland-street, Edinburgh. Tenders, Nov. 7.

RAILWAY CARRIAGES, *South Eastern*.—For the supply of 80 new first-class, 20 new composite, and 25 new second class carriages, and 25 new brake luggage vans. Drawings, specifications, and patterns at station master's office, Bricklayer's Arms railway station, Old Kent-road, or further information of the company's carriage and wagon superintendent, Ashford, Kent. Sealed tenders endorsed "Tenders for Carriage Stock," to be delivered to S. Smiles, secretary to the Company. No date given.

FILTER BEDS.—A filter is required to be made. Apply to J. H. and R. C. Rawlins, Hope Mills, *Wrexham*.

SEWERAGE WORKS, *Scotland*.—Execution of the sewerage works within the burgh of Portobello. Plans and specifications of the works may be seen at the offices of the Commissioners of Police, Portobello, and schedules of measurement, and any information required from Mr. Paterson, C.E., surveyor, 20 St. Andrew-square, Edinburgh. Tenders with Mr. A. Paterson, clerk to the commissioners, Nov. 5.

SEWERING, PAVING, &c., *Manchester*.—For the draining, paving, and flagging of Smedley-road, from its junction with the Queen's-road to the river. Sealed tenders to chairman of committee, Tuesday, Nov. 1st, at the Town Hall, York-street, Chesham. Plans, forms of tender, &c., Mr. William Francis, surveyor, Town Hall, Chesham, Margate. For the erection of a new congregational church, Margate. Plans, &c., J. Denby, Esq., Union-crescent, Margate. Information and bills of quantities, Messrs. Poulton and Woodman, architects, Reading. Tenders to Nov. 1st.

CORN EXCHANGE, *Wellinborough, Northamptonshire*.—For the erection and completion of a corn exchange and public rooms at Wellinborough. Drawings, &c., at the office of E. Sharnham, Esq., architect, Wellinborough. Further information Messrs. Bolland and Hardy, architects, 30 Broadgate, Lincoln. Tenders, Nov. 8th.

ROADS, *New Whittington, near Chatterfield*.—For the whole of the works required to be done in the formation and construction of certain roads and sewers at New Whittington. Specifications and copies of quantities at the Wellington Hotel, Whittington, or Messrs. Senior and Wade's office, Barnsley, to the 30th Oct. Tenders, Oct. 31st.

CEMETERY, *Bath*.—For opening the ground for a cemetery in a piece of land situated behind the toll-house in the Lower Bristol-road, seven feet deep, and providing and placing in side drains 4-inch, and in the main drain 6-inch stoneware socket pipe. There will be about 300 yards of side and 250 yards of main drain. Tenders to Mr. J. G. Hayden, clerk to the burial board, No. 3 John-street, Bath, to Nov. 5th.

DESIGNS, SPECIFICATIONS, AND ESTIMATES FOR REBUILDING THE PARISH CHURCH, *Stroud*.—An organ, chapel, and vestry to be constructed at the side or sides of the church. A premium of £20 for the design approved. Plans to Messrs. Sidney, Bidwell, and G. Edwards, Esq., Secs., Stroud, by Nov. 1st.

DESIGNS AND ESTIMATES FOR CEMETERY, CHAPEL, AND LODGE.—With entrance gateway and boundary wall. Bath. £10 10s. for the selected design should the architect not be employed to superintend the works. A plan &c., to be seen Mr. J. G. Hayden, 3 John-street, Bath. Designs and estimates to Nov. 8th.

FOR THE PURCHASE OF TIMBER.—Larch, spruce, ash, beech, and other timber, and the underwood, in the parish of Millington, near Pocklington, belonging to St. John's College, Cambridge, to be pointed out by Mr. G. Brigham, of Millington. Tenders to the Bursar, of St. John's College, Cambridge to Nov. 7th.

BOILER INSPECTOR.—Wanted, a sound practical mechanic thoroughly acquainted with the details of steam engines and boilers, to act as a district sub-inspector. A knowledge of indicating engines required. Salary, £120 per annum.—Apply by letter, before 1st Nov. next, enclosing testimonials, to H. W. Harman, Esq., C.E., the Association for Prevention of Boiler Explosions, Manchester.

SMITH AND ENGINEER for the Industrial School at West Ham. Married man preferred. Wages 30s. a week without rations or residence. Apply in hand-writing and with testimonials to guardians of Whitechapel Union Workhouse, Charles-street, Mile End, New Town, by 6 p.m., Nov. 1. Personal attendance also.

IRON MERCHANTS' TRAVELLER.—An experienced man who can give satisfactory reference and security.

ENGINEER'S BOOKKEEPER.—To keep a set of books in an engineering factory where from 50 to 100 men are employed.—Must be qualified to take out quantities, keep stock, and price cost book. Apply, stating age, salary required, and reference to Mr. G. Bower, St. Neot's, Huntingdonshire.

TWO ENGINE KEEPERS, at the weekly wages of £1 each, with the usual rewards for the vestry of St. Mary, Islington. Applications on or before Monday, 31st inst., at 6 p.m. Personal attendance at that time, at the vestry office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 4, 1859.

THE WRECK OF THE ROYAL
CHARTER.

MANY circumstances conspire to make the wreck of the Royal Charter one of the most melancholy disasters on record. Not only are there the facts which must strike every mind—the unexampled quickness of the passage from Melbourne; her loss almost within hail both of a harbour of refuge (Holyhead) which she had just passed and of the port for which she was destined; the wholesale swallowing up of almost all on board, and so forth; but there are other facts which are not so well known, but which add greatly to the sadness of the event. The Royal Charter, it will be recollected, was the ship in which the late Dr. Scoresby made a voyage to Australia and back expressly to observe and correct the errors of her compasses, so that the risk which iron ships run from compass errors was probably reduced in her case below that of every other vessel in our mercantile navy. Then again, the Captain who had command of the ship when she met her fate possessed the rare advantage of having made a long voyage in the vessel simply as a passenger, and therefore with ample leisure to study her qualities; for in 1856 Captain Taylor was sent to Melbourne in the Royal Charter by Messrs. Gibbs, Bright, & Co., to fit and bring home the William Monies, an old East India ship, and he made the voyage in her accordingly. Again, while it appears from the narrative of her first voyage that her complement of men and officers was then only about 85, at the time of her loss it was no less than 112, and she therefore had a most excellent chance of being handled efficiently. It was in despite of all these advantages that the Royal Charter came to grief.

It will not do to dismiss this event as a pure piece of misfortune altogether beyond the prevention of man, as some writers have done. One of our London morning journals tells us, for example, that “this melancholy catastrophe was not the result of negligence or over-confidence on the part of any one. . . . No prudence could have averted the disaster.” This view of the matter may appear correct to some minds, but it certainly is not borne out by facts. The *Times* of Saturday last doubtless gave the true view when it said, “the origin of the calamity seems to have been that in a wild night, with a gale blowing that soon became a hurricane, the ship was brought up dangerously near a lee shore.” It was doubtless graceful and generous of the *Times* to add, “let it be remembered, however, that Captain Taylor was the last man seen alive on board;” but gallantry in his death cannot atone for unskillfulness in the life of a man to whose hands 500 other lives are committed. It is necessary to remind the public of this, because we cannot hold Captain Taylor innocent of error without drawing absurd and dangerous conclusions from the loss of his ship. The writer whom we first quoted, for instance, goes on to lament “that no application of human ingenuity is able to withstand the elemental rage,” which, in itself, may be true, but which, nevertheless, implies an untruth. The Royal Charter may have been unable to “withstand” the elemental rage, but she was quite capable of retiring before it, and seeking shelter from it, had her journey not been persisted in after it became perilous. The evidence of the boatswain's-mate of the ship shows that at about eight o'clock on

Tuesday evening the ship was “abreast of the Skerries, distant about a mile and a-half.” The wind had been so high all the latter part of the day that Holyhead had been held in sight for seven hours, and at this time (8 p.m.) so strong a gale was blowing that the ship made little or no progress, but was being carried by the wind and tide towards the shore. The *Times* correspondent at Holyhead, in his account of the Great Eastern's dangers, tells us that there the wind was east at eight o'clock on Tuesday evening; and on comparing all the reported statements, it appears that the gale blew from about the north-east upon the Royal Charter. Now, had the Captain put his ship round at this time, giving her as much sail as she could well bear, there was nothing whatever to prevent him from running either back into the open Channel, or into Holyhead harbour, with perfect safety. With no pilot on board he could not hope to enter the Mersey, and to go on, under such circumstances, with the gale growing to a hurricane, was mere madness. Yet on he went, actually seeking the lee shore which he might have avoided—beating along the perilous north coast of Anglesey, until point Elanus (or Lynus) was passed, and a dead lee shore, of the cruellest kind, was well behind him. Nothing now was left but to “withstand the elemental rage,” and anchor was accordingly cast. All the rest followed naturally enough. The anchors or the cables failed, the masts were cut away, the screw was thus fouled, and the ship went on the rocks. There are, it is true, some discrepancies in the various published narratives as to these occurrences, some stating the masts were cut away and the screw fouled before the ship struck, and others alleging that when she struck the screw was not fouled, but was put on at full speed to harden the wreck on shore; but these details are of no great moment. The fouling of the screw is always a very sure consequence of the cutting away of the masts, whether it occurred sooner or later in the present case.

Another false conclusion which has been drawn from the loss of the ship is, that the use of the auxiliary screw in passenger ships is baneful. The writer of a leading article in a respectable morning journal says, “we are guilty of no presumption in drawing one conclusion, and that is the worse than uselessness, the absolutely fatal mischief, of the so-called ‘auxiliary’ screw.” This remark is supported by the reflection that had there been no auxiliary steam power in the Royal Charter she would never have been permitted to hug “a lee shore at night in search of a pilot, with a hurricane dead on her weather bow, and a strong in-draught to the shore.” The reflection may be sound, but the conclusion is nevertheless untenable. We cannot afford to give up the advantage of steam power because here and there a man relies too much upon it. In the Royal Charter herself the auxiliary screw has proved of immense advantage. Dr. Scoresby, in his narrative of her first voyage, says, “Our quick transit across the first two belts of light winds and calms (on the journey out) by the aid of our auxiliary steam power, is a result, being one generally to be relied on, which must give special advantage and popularity in Australian voyages to ships possessing this appliance, of far more consequence in passage ships, as a relief from protracted oppressive seas, risk of sickness, and actual suffering, than even from the gain of time in the general passage.” Again, he says, “Three or four times an attempt was made (during a calm on the voyage home) to improve our progress by setting the lower topsails, but in all cases the disadvantage in direction was far more than

the gain in speed. They seldom remained on trial for more than an hour or two. The steam-power, small as it was, was our grand resource, giving us generally a six-knot speed, and ordinarily yielding us a progress of 140 miles or more in distance, and a gain of 2° or 2½° in north latitude.” And in another place the Dr. states that the Royal Charter overtook a vessel on the homeward voyage, and found that her own steam power had enabled her to gain 4,000 miles upon the other vessel in 40 days; “the great advantage of possessing this peculiar appliance admits,” he adds, “of perpetually recurring proofs.”

The fact is, the Royal Charter has fallen a sacrifice to an undue passion for short voyages. A too great eagerness to reach the Mersey carried her on to the rocks of Anglesey. But few know what risks are now run in these “fast ships” in order to secure distinction in this respect. This fact also may be illustrated by reference to a former voyage of this very ship. The first gale that ever blew upon her, and which lasted with variations for 40 days, was made to drive her through more than 8,000 miles of distance, under a pressure of sail which would have proved fatal to her and all on board had any failure in the steering-gear, or any defect in its management, occurred. “No one experienced in scudding before a fierce gale and a heavy sea, and knowing how the safety of the ship depended on the steering,” said a passenger then on board of her, himself formerly a captain of merchantmen, “could contemplate the possible failure in apparatus, gear, or management of the helm of the Royal Charter, when so scudding under the violence of this terrible cyclone and tremendous sea, without much anxiety.” This is the sort of thing that is happening every day, the sole reason being that men in these days make so much unhappy haste to be rich, forgetting the proverb, “He that maketh haste to be rich shall not be innocent.”

There is another consideration which we dare not suppress. There seems great reason to fear that the Royal Charter was really a very inferior ship—inferior, we mean, in point of strength. It is difficult to believe that a well-constructed and well-built ship—a ship formed of good material well put together—could have become so utter a wreck as she became in so short a time. This is a matter which may be, and should be, inquired into. Portions of the iron of her hull may be obtained and examined, and the detailed drawings of the ship may be got at. Let this be done. Let, also, as much information relating to her actual construction as can be obtained be secured, that we may ascertain, if possible, why she yielded so swiftly to seas which some ships, some iron ships even, would have withstood for many hours, not to say days. There are other facts, beside that of her rapid break-up, which indicate great weakness in the Royal Charter. On her very first voyage she had to put back to Falmouth, after being six days out, in order not only to improve her trim, but to make her sound and water-tight if possible. “From the day after our sailing,” says a passenger, “much wet had passed through the seams of the deck, by the skylights and bulls-eye lights, screw-bolts, &c. After the commencement of the westerly gale, the water had flowed down in such quantities that all the third-class, and most of the second-class, and some of the first-class cabins were more or less flooded.” This looks like the result of weakness. Moreover, on this and the return voyage her straining was much complained of. On the latter she leaked very considerably in the foremost compartment,

requiring a donkey-engine to keep the leak under. "But the source and anxiety of alarm," says Dr. Scoresby, "was the discovery of weakness and too susceptible working of some of the plates and angle-irons near the junction of the stem with the keel. Some support had been applied within to the upper part of the weak place; but the apprehension of a risk of forcing off the plates had hitherto prevented any appliance to the latter part, where as the external pressure varied as the ship plunged, the working was most considerable. The compartment itself, happily, was but small, and it was thought to be securely water-tight, having in the outset of our voyage been filled, as a tank, with fresh water. But in the case of plates working loose, or, by working, cutting off the heads of the rivets, as was feared, it was impossible to calculate on what the effect of the entire displacement of a plate or plates in the bow might be, or where the mischief might end." It is impossible to read these statements and not see in them an indication of that defectiveness of construction which seems to have manifested itself so fatally in Dulas Bay. The thing most to be apprehended in such cases is, however, inferiority in the iron of which the ship is built. We know that much inferior metal is sold as "ship iron," whereas there is scarcely any work in which excellence of material is more to be desired than in that of shipbuilding. This state of things should be remedied. In the name of Christian charity let us not expose our fellow-creatures to violent deaths, 500 at a time, for the mere difference in the price per ton between good and bad iron!

CUNNINGHAM'S SYSTEM OF REEFING SAILS FOR THE ROYAL NAVY.

We have from time to time in this journal alluded to Mr. Cunningham's system for working the square sails of ships, more especially with reference to its extensive use in ships of the mercantile marine. It is now with much pleasure that we observe its introduction into ships belonging to the Royal Navy.

About a year and a half ago Her Majesty's troop-ship *Perseverance* was fitted at Portsmouth on the "Cunningham system," upon the application of her late commander, John McDonald (who has thus been the means of introducing the system into the Royal Navy); and lately Her Majesty's ship *Urgent* has been also fitted at the same port upon the pressing request of her spirited commander, W. H. Hire. The first use of the system in Her Majesty's Navy was entrusted to Commander Edward R. Power, of the *Perseverance*, an old and experienced officer, who, after two voyages to the Mediterranean and one round the Cape of Good Hope in the winter time, has been called upon to report on the invention. We have been favoured with a perusal of the official report, from which we extract the following very striking passage:—"In variable winds and squally weather, Commander Power was able to make sail, and relieve the engines, when, with the ordinary topsails, it would not be judicious even on account of harassing and exposing the men to continued wet clothing, the efficient number in the watch of Her Majesty's ship *Perseverance* being so small."

We must now call attention to the following extract from a small work published by Mr. Cunningham six years ago, on the sail-power of steam-ships, by which it will be seen that the views which he then held regarding the advantages of his system to screw steam-vessels have been faithfully realized in practice:—"Hitherto I have only treated of my inven-

tion with reference to sailing vessels; but a very important consideration of the subject attaches itself to steam-vessels, and particularly to those fitted with screw propellers. I will, therefore, proceed to point out how peculiarly adapted my invention is to steam navigation. It has been shown that the topsails can be reefed by few men, and that, too, without the exercise of any particular nautical skill. On reflecting on these two very striking considerations, viz., that the operation which now requires the assistance of the whole crew, and all the nautical ability of the ship, can be accomplished by a fraction of the number, and those untrained seamen, the impression cannot fail to be received, that such an invention is peculiarly suitable to screw steam-vessels, and so it is. There cannot be a question but that a steam-ship, whether propelled by screw or paddle wheel, should be in all respects as perfect a machine as possible. The utmost ability of man has been directed towards this object, so far as the steam power is concerned, but hitherto, although, by the application of the screw propeller, the steam power remains no longer a principal, but the sail power resumes its ancient importance, and the steam may be viewed only as an auxiliary; still, the bringing of that sail-power under mechanical control appears to have been entirely lost sight of. The object which has occupied the attention of the ablest engineers for years to accomplish, viz., to bring the navigation of a ship as much as possible under the control of machinery, is thus overlooked, and the steam-ship is relapsing into the same troublesome machine to navigate that it was 100 years ago, indeed more so, for the immense yards and sails of our large ocean screw ships are disproportionate to the number of seamen comprising their crews; and hence, in fact, all that has been gained by the exercise and practice of years of profound mechanical science, ingenuity, and skill, is that sailing ships can be propelled in a calm, and otherwise assisted by auxiliary steam-engines; but most gravely must it be considered, that this advantage has been obtained at the sacrifice of an immense original expenditure of capital, the requirement of an enormous sustaining outlay, the sacrifice of room for stowage, and other negative considerations which really make it questionable whether any advantage has been obtained at all, particularly as it does not appear that the brevity of the passages made by our large screw steam-ships in any way compensates for the vast expense involved in their support.* I maintain, therefore, that one thing is yet required in a screw steam-ship, or indeed any full-rigged steam-vessel, and that is, to bring the sail power more under mechanical control. This will not only afford the means of reducing expense, by removing the necessity of having a large crew of trained seamen, but it will also give encouragement to commanders to make as much use of their sails as possible; it being reasonable to suspect, that under the circumstances of large powerful sails, and with few men to work them, sail is often taken in, when otherwise it might be carried; such may be inferred from the fact of many sailing ships having made quicker passages to and from Australia than the large and costly screw steam-ships." Commander Power's report quite corroborated Mr. Cunningham's expectations, and the consideration for his men displayed by the Commander is an interesting feature in his report.

There can be no doubt that the question of improving the mechanical appliances for working the sails of ships, especially steam-ships, had

become one of great importance. It was time to break out of the antiquated systems of ages, and at least attempt an improvement in this branch of nautical mechanical science, in which there has not been any marked change for upwards of 200 years. The introduction, therefore, of Mr. Cunningham's invention into the Royal Navy is a striking event in its history; and Commander Power's duty of making the first use of it has been an important one.

Although we have reason to know that the principal object which Mr. Cunningham had in view when he devoted his time and ability to the great work of introducing his invention into the mercantile marine was the saving of life; still, as the advantages and capabilities of the plan developed themselves, other considerations were suggested, and the expediency of applying it to ships of war was entertained. We again quote an extract from Mr. Cunningham's work before-mentioned bearing on this point:—"Hitherto I have confined myself to considering the applicability of my invention to the mercantile steam navy, but it may further be considered how far suitable it is to steam ships-of-war. In action, the tactics of a war steam-ship would doubtless be to depend on the control of the steam-power alone; the failure, however, of that power by damage to the machinery would necessarily oblige her to have recourse to her sails; and the ability to apply the sail power with the utmost celerity, and without exposing men aloft, would become an object of the greatest importance. Here, then, the advantages offered by my invention are very apparent. A steam ship-of-war, rigged and fitted in the manner before described, would be enabled to go into action with her topsails and topgallant sails rolled snugly up on the yard, yet ready for instant setting, without exposing men aloft. The ability thus afforded would not only give the ship a superior advantage in the event of her machinery becoming disabled, but would also enable her to use any of these sails with great facility and effect in assisting in the tactical movements of the ship."

We know that a reason given by naval officers for not using the Cunningham system in the Royal Navy is the necessity which there exists for keeping up the old method of working the sails, in order to exercise the crew aloft. This no doubt is very desirable, especially as it is to be feared that our seamen are not possessed of the same agility and skill that some years ago so greatly distinguished them from the seamen of other countries. But still, Mr. Cunningham's brief remarks on the application of his system to ships-of-war deserve serious attention. Steam-power has greatly altered the features of naval warfare. We shall no longer have, as a rule, fleets engaging each other under sail, when superior seamanship affords an advantage. Steam-power levels all these considerations, and the fleet which possesses the most expert artillery-men will be the most likely to win the battle. Why, then, cling pertinaciously to the continuance of exercises which occupy valuable time that would be well devoted to gunnery instruction. We shall watch the progress of Mr. Cunningham's valuable invention in Her Majesty's navy with much interest; and we trust at least that the equipment of Her Majesty's ships *Perseverance* and *Urgent* is the prelude to the fitting of all the troop ships and other short-handed vessels in the service.

The circumstance that the Cunningham system is now fairly introduced into the Royal Navy suggests the expediency of some means being adopted for the instruction of officers in the use of it. We hear that its operation is as simple as can be possibly conceived, and that

* We dissent from this. See previous article.—Eds. M. M.

Mr. Cunningham has published copious instructions for the working of it. But still the proper practical working of it requires, no doubt, some previous acquaintance with its mode of action; and we can conceive the embarrassment of an officer of the watch being called upon to reef the topsails on a dark night by a method which practically he knows nothing about. Mr. Cunningham has a small yacht brig at Portsmouth fitted on his system, and he takes great pains to get the officers of ships fitted with his plan on board to instruct them in the working of it. But although this individual effort may answer its purpose as regards these particular officers, still, a general knowledge of the working of the system appears to be most desirable, especially with reference to the younger officers now being brought up in the service. The mizen-topsail of the school ship Conway, at Liverpool, is already fitted to instruct the lads in the new mode which, in the mercantile marine, is becoming almost universal; few new ships being now built without it, and a very large proportion of them already built being equipped on the "Cunningham system." The result of all this will be that in a short time the rising generation of officers, and, in fact, of seamen too, of the mercantile marine will know nothing about the old method of reefing topsails, and the officers of the Royal Navy will be equally ignorant of the new, with the exception of those officers who may have served on board Her Majesty's troop-ships fitted with the system. Whether, therefore, the system becomes general in the Royal Navy or not, the instruction of officers, and especially the rising generation, in the practical working of it, really becomes a subject demanding the consideration of Government.

We understand that there is something remarkable about the fitting of the Urgent. The yards of men-of-war are constructed in a different manner to those of merchant ships. The former are furnished with oak battens of considerable thickness towards the centre of the yard secured by hoops, while the merchant ship yards are without these battens. However, Mr. Cunningham has fully conquered any difficulty that might appear to exist, and the yards of the Urgent are remarkable for their snug appearance. Another peculiarity in men-of-war is, that they reeve their topsail-tyes through blocks upon each side of the topmast, while the ties of merchant ships are generally led through sheave-holes. Mr. Cunningham has met this by having two neat iron blocks placed well forward on the topmast, which brings the lead of the chains nearly up and down. The advantage of all this has been, that the new system was applied without even the topmasts being sent down; indeed, from the time the iron work arrived from London, the yards and sails were all completed and ready to go aloft in *three days*. These are important considerations with reference to ships of war, as it shows that they can be very quickly altered to the new system, and without involving any great change aloft. It shows, too, that if need be the sails and yards can be fitted with the reefing gear, and yet still be used on the old plan for purposes of exercise; the reef becketts can be kept on the sails, and the toggles on the yards, and without interfering with the working of Mr. Cunningham's system, provided that the reef earings are unrove before the yard is worked. This is very important.

Mr. Cunningham in the work before alluded to points out the ability which his invention affords of sailing ships with fewer regular seamen in their crew. He instances a case where a ship, during the late war with Russia, proceeded to sea with a crew a large proportion of

which were brickmakers; he also quotes the case of an American ship, the Hurricane, of upwards of 1,500 tons, having been navigated from Hong Kong to San Francisco with only twenty-five Lascars and three European seamen; neither of which, of course, could have been done if these ships had been rigged on the old plan. Now this appears to us to possess considerable political importance. There is no doubt that should we be ever again involved in a long Continental war, and the requirements of seamen for the Royal Navy be very large, as they will be, the only source from which we can look for seamen for the navy is the merchant service. The power, therefore, which the shipowner now has of sailing his ships with fewer regular seamen, would prevent the serious injury to trade which a large drain of seamen from the merchant navy would occasion. Moreover, it would help in a measure towards manning the navy in an indirect manner. The landsmen who would be entered on board the merchant ships to make up their crews would, after a few voyages, be eligible for ordinary seamen in the navy; and thus, indirectly, the supply of seamen would be kept up. It must be remembered that upon the old system few landsmen were entered on board of merchant ships; the shipowner could not afford to pay far labour comparatively useless to him; hence the few seamen which composed the crew were necessarily obliged to be skilled seamen, to do their duty aloft. It is not so now: the sturdy peasant will be as useful in heaving the anchor up and putting his strength to the ropes on deck, after he has got over his sea-sickness, as the seaman.

We may have occasion again to say a few words on this interesting subject. The fact is clear that a very important and marked change in the mode of working ships has been steadily establishing itself in the mercantile marine, and is now making its way into the Royal Navy, which involves deeper considerations than are at first sight of the subject perceived; and as a great maritime country we cannot but look at this change with the deepest interest. Although so dependent on our marine for our security and our glory, we have, as it were, until lately, most unaccountably been slumbering upon the subject of it. During the past forty years mechanical science of every description has undergone change and improvement, but the *sail* appears to have been comparatively lost sight of. It is true that the utmost energy and talent have been devoted to the perfecting of the application of steam propulsive power; but, to use Mr. Cunningham's term, the sail power has been neglected. That power which costs nothing, and by the mighty aid of which the new world was discovered, and the ends of it brought together, has not had its value properly esteemed. Its application to purposes of propulsion remained, until the production of Mr. Cunningham's invention, in the primitive condition of ages past.

Since commencing these remarks, we have received information to the effect that another of Her Majesty's troop ships has been ordered to be fitted by Mr. Cunningham—Her Majesty's ship Vulcan, at Portsmouth, at the request of Commander Strode, who commands her.

UNSINKABLE SHIPS.

THE extraordinary changes which modern ordnance has undergone, and is still undergoing, have led to many curious suggestions, and among the most curious may be mentioned a scheme first propounded by Mr. Charles Atherton, of Woolwich Dockyard, in the *Times* of Jan. 12, and the *MECHANICS' MAGAZINE* of Jan. 14, 1859, and revived by him in a recent

number of the *Journal of the Society of Arts*. Mr. Atherton's object in the first instance was to make gun-boats, mortar-boats, floating-batteries, &c., invulnerable; and he asks—Why not make them up to the lines of their load displacements "solid masses" of material, of such specific gravity that they shall not sink however much they may be perforated by shot? He considered that a solid combination might be made of cork shavings, light wood sawdust, rush stems, cotton waste, flock, hemp, and other light material, by the aid of a solution of gutta-percha, or other chemical substance. This mass might be made, he thought, so tough that it could not be knocked to pieces by shot, and so light that it would be only one-half the specific gravity of water, and therefore unsinkable, however perforated by shot, and also capable of carrying an armament and naval equipment to the extent of nearly one-half the weight of its own displacement in tons. "Such vessels" of light draught accompanying fleets of war as "tenders to line-of-battle ships, whence they might be manned and stored as occasion might require, would, I submit," said he, "form a useful auxiliary available for shore service, or for attacking land batteries, which deep draught ships of the line cannot approach, and would be sunk if they could." The idea was first broached by him two years before as being applicable to the construction of vessels for carrying treasure.

In the interval that elapsed between the dates of Mr. Atherton's letters his ideas appear to have expanded enormously. We no longer hear of unsinkable "tenders to line-of-battle ships" only; but ships of war of all classes are to be constructed on the unsinkable principle. "I have no doubt," says Mr. Atherton "that at a moderate cost per ton of shipping, existing vessels may be rendered unsinkable, and that a new modification of ships of war of all classes may be devised, such as may obviate the horrors which appear to be otherwise inevitable in maritime warfare under the fire of modern ordnance." It ought to be stated that Mr. Atherton's reason for renewing his proposition at the present time, and in its enlarged form, is a belief of his (founded on a paragraph in the *Times*) to the effect that iron-cased ships will be incapable of resisting the fire of modern ordnance, and that, as recent events have shown, ships of the ordinary build may be sunk by the fire "even of an extemporised Chinese fort."

There is, of course, one great primary obstacle to the carrying out of Mr. Atherton's plan, namely, that no such material as he requires for his purpose is at present known. The singular compound mentioned in his first letter does not seem to satisfy him now, and he therefore proposes that £250 be subscribed and placed at the disposal of the Council of the Society of Arts, to be awarded in premiums of £150 and £100, "for the discovery and specification of the materials and process of manufacture most available for producing a combination of materials constituting a solidifying pulp possessing in the highest degree the properties of specific lightness, toughness, non-absorption of water, and cheapness, or a metallic cellular body having the same properties." But how a "metallic cellular body" is to answer the purpose we cannot conceive. It seems to us a very remarkable circumstance that Mr. Atherton loses sight altogether of the danger of fire, which is more likely to do injury than anything else now that the use of shells is universal in naval warfare. His light buoyant material must be presumed to be exposed to the fire of ordnance, for its whole merit is to consist in being unsinkable when "perforated."

by shot or shell; and, consequently, unless it were unflammable as well as unsinkable it would be of little use. Mere "lightness," "toughness, non-absorption of water, and cheapness" alone will not therefore do. If we are wrong in this we shall be glad if Mr. Atherton will show us where our error lies; but he must not forget that "liquid fire" is as veritable a means of offence as the Armstrong gun, and has proved its efficacy quite as decidedly. Of course we are quite aware that a solid substance would not be set fire to by the mere lodgment of a red-hot shot in it, with no other access for air save the hole by which the shot entered. But the explosion of powerful shells within such a substance would be a very different matter, and would, we think, in most cases have the effect of setting it on fire. There can be no great harm in offering the premiums proposed by Mr. Atherton if there is the least chance of obtaining a very light fire-proof and water-proof solid material, because such a material would be useful for many purposes; we have no desire, therefore, to obstruct the action of the Society of Arts in this matter.

But, having said this, it remains for us to say further that even if such a material as we have spoken of should be produced, and placed in Mr. Atherton's hands, we should be disposed to ask wonderingly—What will he do with it? and we think the Society of Arts should consider this question before they accept his advice respecting the premiums. With a ship solid below the water-line where would he place the engines, coals, provisions, powder, and all those other stores which now are stowed in the lower parts of the ship? We know not how to conceive a plausible answer even to this question. Will Mr. Atherton kindly help us out of the difficulty? We hope he will, if possible, for his own credit's sake. It is easy enough for any man to make propositions in the form in which the present one comes before us; but it will not do for a gentleman who has taken a wrangler's degree at Cambridge, and made himself prominent in scientific discussions, to leave his propositions utterly undeveloped. It is, we think, incumbent upon Mr. Atherton to show us what the "new modification" of ships of war is to consist in, assuming that the material which he asks for is supplied. We should be heartily delighted to find that he has the design of the unsinkable war-ship in his mind. This, in our judgment, would be worth a very handsome "premium," and the Society of Arts would perhaps do well to offer one for it before they offer the others. They need not fear any very extensive competition. Of course it is quite possible to build enormous rafts, and call them by the new name of "unsinkable ships"; but these can hardly be what Mr. Atherton is thinking of, since he talks of rendering "existing vessels" unsinkable, and since he must know perfectly well that the time for abandoning real ships has not yet arrived. What, then, is he thinking of? We respectfully invite him to tell us.

COINING BY CONTRACT.

It is not without an intense feeling of dissatisfaction that we have observed a paragraph "going the round" of the newspapers intimating, in terms too positive and plain to be misunderstood, that the Government intend putting the coining of the new mixed metal monies out to contract. Our readers are well aware that the proposition for re-organising the inferior coinage of England was first promulgated—at the commencement of the present year—in the pages of the *MECHANICS' MAGAZINE*, and since that is the fact we naturally assume to ourselves the right of comment upon

the mode to be adopted in the realisation of the great reform. There is no manner of doubt that the establishment for making the national monies—the Royal Mint—might, with an amount of outlay upon new mechanical appliances and fittings inconsiderable in comparison with the advantages to be derived therefrom, be made quite equal to the task of which ministers have assumed the responsibility. The four or five hundred tons of bronze coins which would have to be pressed into being before the old copper could be entirely superseded would, with little expense, in the course of less than three years, and without any interference with the production of gold and silver coins, be struck on Tower Hill. Why, we ask—and the public no doubt will reiterate the question—"why are we to have a contractor in Birmingham—ham employed to do the Mint's work?"

To us such an arrangement seems inexplicable. There is no sort of manufacture conducted by Government which requires in all respects so much caution and care as that of money, and no manufacture, therefore, which should be more jealously hedged in by restrictions and reservations. But here, without any shadow of good, pecuniary or otherwise, the carrying out of a great reform in the coinage is, to be entrusted to hands whose interest is not to produce pieces of money so perfect as to defy the cunning labour of the counterfeiter, but such as shall return the greatest amount of profit to themselves. Surely the Chancellor of the Exchequer has not thought sufficiently upon the subject, or he would not have sanctioned so gratuitously dangerous a proceeding. We say "have sanctioned" it, because from the terms of the paragraph in question it appears that sanction has positively been given to it. Let not the singularly favoured and fortunate firm in Birmingham who have obtained, without competition, at least the promise of being entrusted with the highly important duty of supplanting the worn-out copper with the new mixed metal coins, imagine that our remarks are at all personal. That would be a great error; our criticisms are based on the laws which govern contractors in general, and not themselves in particular. They may, for aught we know to the contrary, be quite as disposed to make themselves worthy of the great occasion as any other firm in the kingdom, but they are subject to the commercial law which bids them "make as much out of the job" as they can. It matters not to us whether it be Messrs. A, B, C, or H, who undertake the task, we say it is not one for contract at all, and that the Government is in error in making it one. But we do not understand why (admitting for a moment that the Institution which we have, and which is kept up at a cost of some thirty odd thousand pounds per annum, is incompetent to the task), specifications should not be put forth to all and sundry engineers, button-makers, breastplate-makers, stampers of gas-fittings, &c., so as to give them also an opportunity of competing for the coinage. That would appear to be a course so completely in order—when once the question of contract or no contract is answered affirmatively—that it is impossible to understand why it has not been done in this instance. When it was proposed by Sir John Herschel, at the commencement of his mastership in 1852, to hand over the entire plant of the Mint to contractors, who were to be bound under heavy penalties to produce coin of proper weight, standard, and finish, and to be always under the control of officers of the establishment appointed by the Treasury, the opportunity of undertaking the contract was offered to the most eminent

engineering firms in and out of London. But in this instance no such course has been adopted. "Kissing" has been said to "go by favour," and so far as that pleasant operation is concerned the saying is doubtless just; but why the privilege of coining the monies of the State is to be subject to the same rule it is not easy to see. Perhaps in the course of two or three months, and when Parliament is sitting, some Member of the Government may enlighten us on the point.

At present, the fact that the initiation of a new coinage on a vastly improved plan, and which is destined to form an era in the minting annals of the country, is to be taken out of the guardianship of Her Majesty's coiners and put into those of a company of Birmingham contractors, is the one to which we have felt it proper to direct public attention, and in omitting to do which we should have omitted our own duty. We publish on another page a copy of the paragraph named, and have merely to say that the *Manchester Guardian* has been totally misinformed in regard to the fact that the firm referred to therein have "executed the copper coinage for this country for many years." We are in a position to assert that they have done no such thing. The Parliamentary returns will demonstrate the fact that from 1805-6, when the last coinage of copper took place at Soho, up to 1852, and from 1855 to 1859, the whole of the copper coins for Great Britain and her Colonies have been executed exclusively at the existing Mint on Tower Hill. If the other statements of the paragraph were as inaccurate as this with regard to the production of copper coin, why, it might be treated with silence; but there is, as we have said, truth in the averment that new engines and new coining presses are being prepared for Birmingham contractors, and we allow the paragraph to speak for itself.

THE GREAT SEAL PATENT OFFICE LIBRARY.

WHAT is to be done in the matter of the Great Seal Patent Office Library? Over and over again the manifest want of increased accommodation, not only for the readers who frequent it, but even for the very books, has been pointed out by the London press, from the *Times* downwards, and yet nothing has hitherto been done. At the present moment the wretched passage which is by courtesy deemed a part of the library itself is actually being blocked up with shelves, in order to afford standing space for the newly-arriving volumes. As the Commissioners of Patents appear to be so entirely neglectful of inventors and others, who contribute goodly sums annually to the State, we turn to Mr. Edmunds, the Clerk to the Commissioners, who must possess considerable influence in the matter, and we ask him to see that something is speedily done. We know he has but little time to give to the subject, because his large private business as estate-agent in the north, coupled with his duties as Reading Clerk and Clerk for Private Bills in the House of Lords (for which he receives but a paltry £1,500 a year), together with other engagements, must necessarily absorb much of his time and energy. But then, as he receives £1,000 per annum from the fees of patentees, we have some claim upon his attention, and would rather have his services bestowed upon the improvement of the library than upon anything else.

For it is perfectly manifest that a public library in connection with the Patent Office has become indispensable. It is the only simple means which can be afforded to inventors for enabling them to act justly to themselves and honestly to each other. There must be a place

in which they can make reference to the specifications of former patents, and to standard works on scientific subjects. Moreover, the attendance at the present gloomy cavern proves how needful a library is felt to be.

Mr. Edmunds must see all this, and we ask him to set upon what he sees. And we do so with the best of intentions, for we assure him that his past inactivity in the matter is inducing people to believe that he is more than inactive—that, in fact, he is hostile to the very existence of the library. It is time, therefore, that he took action, and proved that he is neither a slothful nor a faithless servant of patentees. A thousand a year may seem a trifle to a gentleman who has passed most of his life in a perpetual glow of patronage, and enjoyed many of the great gifts which Lord Chancellors and ex-Lord Chancellors are able to bestow. But to plainer men a thousand a year seems a considerable sum, and one which no man should put in his pocket until he has done something in return for it. This is the kind of thing that patentees are beginning to say, and it is only right that the gentleman in question should know it.

We appeal, therefore, to Mr. Edmunds. We are tired of appealing to Sir Richard Bethell, Sir Henry Keating, and their colleagues, although they really ought to support us cordially in this matter. Sir John Romilly, above all, being the only permanent Commissioner, ought to do his best for us. But Mr. Edmunds is the executive officer. We turn to him in this emergency, and we shall continue to look to him until something is done. We shall not cease to urge our claims upon his attention until our legitimate and pressing demands are complied with.

SUBMARINE TELEGRAPH CABLES.

It is useless to conceal the fact that submarine electric telegraph cables, as hitherto constructed, have been to a very great extent failures. There is great reason to doubt whether their insulation has ever been perfect even when they have left the manufactories; in many instances they have been greatly injured in transport from the works to their destinations; they have very frequently sustained great damage in the paying-out process; and, finally, they have been far too susceptible to injury even after submergence. All these things, of course, entail great expense and loss upon the proprietors of the cables—who are generally the shareholders of companies—and it is not at all surprising that effectual remedies have been sought.

With these facts before them, some persons have leaped to the conclusion that gutta-percha, which has been used as the insulating material in most of these failing cases, is not a suitable material for the purpose; but we are by no means prepared to go this length with them, because we know that much of the mischief has arisen from causes not at all assignable to the intrinsic qualities of the insulator. At the same time, whatever there may be to say in favour of gutta-percha, it appears beyond question that pure india-rubber is, to say the least, in all respects equal to it in this respect. Pure india-rubber properly applied is, in fact, a perfect insulator. Its proper application is, however, a matter of immense importance. How, then, may this be effected?

We honestly confess that we know of no method by which this is to be done with the same certainty of a good result as is secured by the system lately introduced by Messrs. Wells and Hall. We have, on a former occasion, directed attention to their plans; but, as we have lately had occasion to inspect the machinery completed for them by Messrs. Easton and Amos, we think it desirable to repeat our refer-

ence to them, especially as a company designed to carry them out is, we observe, in course of formation. Messrs. Wells and Hall—who, it should be remembered, have been engaged for many years in the manufacture and application of india-rubber in all its various forms—do not themselves hesitate to pronounce pure rubber much superior to gutta-percha for insulating the conductors of submarine telegraph cables. They tell us that, proceeding upon their own practical knowledge, they have selected as their insulating agent pure india-rubber, which has never before been used for the purpose, and which is capable of bearing much severer tests than it is possible for gutta-percha to sustain. "It is a well-known fact," they say, "that gutta-percha is a very impure gum, and has in it a very large portion of woody substance, which must decay, and ultimately destroy the insulation. Moreover, gutta-percha is liable to be very seriously injured by changes of temperature, which must consequently affect the insulation to a very considerable extent. The patentees, therefore, consider that the use of pure india-rubber, as applied according to their method of insulation, is the only permanent remedy for the frequent failures which occur in the insulation of submarine cables. The india-rubber used in its pure state has," they continue, "many advantages which gutta-percha does not possess. It is perfectly free from grit and every other impurity; it is also permanently elastic and capable of bearing without injury a very high degree of temperature, which is a most essential quality for all cables that have to be forwarded to various parts of the world. Telegraph companies are therefore assured that the cables manufactured by them will not be destroyed either by the process of paying out or by lying in the holds of ships while proceeding to hot climates. "The method of applying the india-rubber according to the patent of Messrs. Wells and Hall, admits of no defects in construction, but insures a certainty of electrical integrity which is altogether unexampled." This is the language of the patentees themselves, and will therefore, of course, be of little value of itself; but we must admit they have grounds for their statement. By winding on successive ribands of the pure rubber, the whole process of manufacture can be watched at every stage, and it is difficult to see how any sort of defect can occur; while, by laying the successive ribands on partially over each other, and in opposite directions, even if a defect should occur in one fold it would be effectually neutralized by the next. These successive layers of india-rubber being again covered by a close-laid elastic cord, become so pressed and amalgamated as to form one perfectly sound and impervious insulator.

The external coverings of the cables thus insulated may be of various descriptions—either all of wire or in part wire, or in part a mixed covering of prepared hemp and wire, as may be desired. The coverings hitherto adopted have usually been made upon the spiral principle. The consequence is, they have a strong tendency to stretch and to kink, which sooner or later destroys the insulation. These evils are entirely obviated by the covering processes adopted by Messrs. Wells and Hall, in which the coverings are braided on in a new and peculiar manner. The machinery employed for this purpose (and which has been made with great care and skill by Messrs. Easton and Amos) is constructed upon the general principle of double hollow tube braiding machines, and so perfectly encases the insulated portions of the cable that the whole tensile strain is brought on the external covering which can be made to

bear any required amount of strain without the least possibility of injuring the insulation, either in the process of manufacturing, or by elongation, or as it is being payed out from the vessel.

There are minor advantages in connection with this construction of submarine telegraph cables of which it is not necessary here to speak, our object being simply to endeavour to get the plan properly estimated. There are enormous interests at work in opposition to all great changes in telegraph cable construction, and nothing but the enlightenment of shareholders and the public will ever operate successfully in favour of improvement. We sincerely hope that the apprehensions which many feel in connection with the Government contracts for cables will be dissipated, and that the authorities will not fail to adopt a thoroughly reliable system of construction.

THE FOUNDER OF MECHANICS' INSTITUTIONS.

MR. CARLYLE tells us, and we all of course believe, that "no lie can live." A lie is repugnant to nature—aye, to God—and all the natural forces of the universe will war with it whenever they encounter it. It does not matter how great may be its origin, or how strong its supporters; it must, sooner or later, be blotted out.

Lord Brougham has this week been repeating at Newcastle-on-Tyne that old and dismal error of his about the founding of mechanics' institutions. George Birkbeck, he again says, was the author of them. "We seconded him, and no more. We laboured as hard as we could, but he began it. He began it twenty years before he established it in London. He began it at Glasgow, where he delivered a course of lectures to working men. This was the origin of mechanics' institutions. He then transferred it to London for the sake of greater extension, and as being a more important place for large support. He it was that propounded it in London also, and not only proposed it and furthered it, but spent large sums of money upon it, which his family have never been repaid. These were the services of Dr. Birkbeck, and he it is that we must call and always treat as the founder of mechanics' institutions. He laboured, we seconded him, no doubt, according to our means in our different capacities. We were his fellow-labourers, but he was the first and the originator of this great step in social progress."

These are Lord Brougham's present statements. He is not insensible to our late strictures, for, in the words which we have put in italics first, he endeavours to avoid Mr. Robertson's claim to be the founder by pushing the origin of mechanics' institutions back to the time of the Glasgow lectures to working men. In the second italicised sentence, however, he makes the distinct assertion that Dr. Birkbeck first propounded the London Mechanics' Institution. The assertion is false—distinctly, unquestionably, demonstrably false! We have before shown why it is so; will Lord Brougham attempt to show the contrary? Assertion, even from him, and, although repeated a thousand times, is not proof. Mechanics' institutions sprung from the MECHANICS' MAGAZINE, and originated in the brains of its first editors, Mr. Robertson and Mr. Hodgskin. If there were no taint in Lord Brougham's noble nature he would say the same.

We are requested to state that that very beautiful building the Temple Church is again open (free) every day from ten till four. Divine Service on Sundays at eleven and three.

ON THE TRANSMISSION OF HEAT OF DIFFERENT QUALITIES THROUGH GASES OF DIFFERENT KINDS.

The following is an authorised abstract of a lecture recently delivered at the Royal Institution under the Presidency of H.R.H. the Prince Consort, by Professor J. Tyndall, F.R.S.:-

Some analogies between sound and light were first pointed out: a spectrum from the electric light was thrown upon a screen—the spectrum was to the eye what an orchestra was to the ear—the different colours were analogous to notes of different pitch. But beyond the visible spectrum in both directions there were rays which excited no impression of light. Those at the red end excited heat, and the reason why they failed to excite light probably was that they never reached the retina at all. This followed from the experiments of Brücke and Knoblauch. These obscure rays had been discovered by Sir Wm. Herschel, and the speaker demonstrated their existence by placing a thermo-electric pile near to the red end of the spectrum, but still outside of it. The needle of a large galvanometer connected with the pile was deflected, and came to rest in a position about 45 degrees from zero. A glass cell, containing the transparent vitreous humour of the eye of an ox, was now placed in the path of the rays: the light of the spectrum was not perceptibly diminished, but the needle of the galvanometer fell to zero, thus proving that the obscure rays of the spectrum, to which the galvanometric deflection was due, were wholly absorbed by the humours of the eye.

Reference was made to the excellent researches of Melloni. In a simple and ingenious manner he had proved the law of inverse squares to be true of radiant heat passing through air, and the eminent Italian inferred from his experiments that for a distance of 18 or 20 feet the action of air upon radiant heat was totally inappreciable. This is the only experimental result now known regarding the transmission of radiant heat from terrestrial sources through air; with regard to its transmission through other gases it was believed that we were without any information.

It was, however, very desirable to examine the action of such media—desirable on purely scientific grounds, and also on account of certain speculations which had been based upon the supposed deportment of the atmosphere as regards radiant heat. These speculations were originated by Fourier, but it was to M. Pouillet's celebrated Memoir, and the recent excellent paper of Mr. Hopkins, to which we were indebted for their chief development. It was supposed that the rays from the sun and fixed stars could reach the earth through the atmosphere more easily than the rays emanating from the earth could get back into space. This view required experimental verification, and the more so, as the only experiment we possessed was the negative one of Melloni, to which reference has been already made.

The energetic action of the solid and liquid compounds into which the element hydrogen enters, suggested the thought that hydrogen gas might act more powerfully than air, and the following means were devised to test this idea. A tube was constructed, having its ends stopped airtight by polished plates of rock-salt held between suitable washers, which salt is known to be transparent to heat of all kinds; the tube could be attached to an air-pump and exhausted, and any required gas or vapour could be admitted into it. A thermo-electric pile being placed at one end of the tube, and a source of heat at the other, the needle of an extremely sensitive galvanometer connected with the pile was deflected. After it had come to rest, the air was pumped from the tube, and the needle was carefully observed to see whether the removal of the air had any influence on the transmission of the heat. No such influence showed itself—the needle remained perfectly steady. A similar result was obtained when hydrogen gas was used instead of air.

Thus foiled, the speaker put his questions to

Nature in the following way: a source of heat, having a temperature of about 300° C., was placed at one end of the tube, and a thermo-electric pile at the other—a large deflection was the consequence. Round the astatic needle, however, a second wire was coiled, thus forming a so-called differential galvanometer; a second pile was connected with this second wire, so that the current from it circulated round the needle in a direction opposed to that of the current from the first pile. The second pile was caused to approach the source of heat until both currents exactly neutralised each other, and the needle stood at zero. Here, then, we had two powerful forces in equilibrium, and the question now was whether the removal of the air from the tube would disturb this balance. A few strokes of the air-pump decided the question, and on the entire removal of the air the current from the pile at the end of the tube predominated over its antagonist from 40° to 50°. On re-admitting the air the needle again fell to zero; thus proving beyond a doubt that the air within the tube intercepted a portion of the radiant heat.

The same method was applied with other gases, and with most remarkable results. Gases differ probably as much among themselves with regard to their action upon radiant heat as liquids and solids do. Some gases bear the same relation to others that alum does to rock-salt. The speaker compared the action of perfectly transparent coal-gas with perfectly transparent atmospheric air. To render the effect visible to the audience, a large plano-convex lens was fixed between two upright stands at a certain height above a delicate galvanometer. The dial of the instrument was illuminated by a sheaf of rays from an electric lamp, the sheaf being sent through a solution of alum to sift it of its heat, and thus avoid the formation of air-currents within the glass shade of the instrument. Above the lens was placed a looking-glass, so inclined that the magnified image of the dial was thrown upon a screen, where the movements of the needle could be distinctly observed by the whole audience. Air was first examined, the currents from the two piles being equilibrated in the manner described; the tube was exhausted, and a small but perfectly sensible deflection was the result. It was next arranged that the current from the pile at the end of the tube predominated greatly over its antagonist. Dry coal-gas was now admitted into the tube, and its action upon the radiant heat was so energetic, the quantity of heat which it cut off was so great, that the needle of the galvanometer was seen to move from about 80° on one side of zero to 80° on the other. On exhausting the tube the radiant heat passed copiously through it, and the needle returned to its first position.

Similar differences have also been established in the case of vapours. As representatives of this diverse action, the vapour of ether and of bisulphide of carbon may be taken. For equal volumes, the quantity of heat intercepted by the former is enormously greater than that intercepted by the latter.

To test the influence of quality, the following experiment was devised. A powerful lime light was placed at one end of the tube, and the rays from it, concentrated by a convex lens, were sent through the tube, having previously been caused to pass through a thin layer of pure water. The heat of the luminous beam excited a thermo-electric current in the pile at the end of the exhausted tube; and this current being neutralised by the current from the second pile, coal-gas was admitted. This powerful gas, however, had no sensible effect upon the heat selected from the lime light; while the same quantity of heat, from an obscure source,* was strongly affected.

The bearing of this experiment upon the action of planetary atmospheres is obvious. The solar heat possesses, in a far higher degree than that of

* The quantity of heat is measured by the amount of the galvanometric deflection which it produces; its power of passing through media may be taken as a test of quality.

the lime light, the power of creasing an atmosphere; but, when the heat is absorbed by the planet, it is so changed in quality that the rays emanating from the planet cannot get with the same freedom back into space. Thus the atmosphere admits of the entrance of the solar heat, but checks its exit; and the result is a tendency to accumulate heat at the surface of the planet.

In the admirable paper of M. Pouillet already referred to, this action is regarded as the cause of the lower atmospheric strata being warmer than the higher ones; and Mr. Hopkins has shown the possible influence of such atmospheres upon the life of a planet situated at a great distance from the sun. We have hitherto confined our attention to solar heat; but were the sun abolished, and did stellar heat alone remain, it is possible that an atmosphere which permits advance and cuts off retreat, might eventually cause such an accumulation of small savings as to render a planet withdrawn entirely from the influence of the sun a warm dwelling-place. But whatever be the fate of the speculation, the experimental fact abides—that gases absorb radiant heat of different qualities in different degrees; and the action of the atmosphere is merely a particular case of the inquiry in which the speaker was at present engaged.*

THE GREAT EASTERN AND STEAM-SHIP ECONOMY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Woolwich Dockyard, 1st Nov., 1859.

GENTLEMEN,—With reference to Mr. Cheverton's objection (*MECHANICS' MAGAZINE*, No. 44, p. 284) "that the formula $\frac{Ind. h. p.}{V^2 D^4}$ does not do

justice to the performance of the Great Eastern in the aspect of commercial excellence, namely, speed in conjunction with great transport capabilities and economic employment of power," and inviting my re-consideration of the subject, I beg to refer Mr. Cheverton to pages 15, 16, 17, and 18 of the appendix to the second edition of my "Essay on Steam-Ship Capability," where he will find the superior dynamic capabilities of large ships, as compared with smaller vessels, in a mercantile point of view, fully recognized and demonstrated by five tables devoted to that subject, namely:—

Table No. 1, showing the SUPERIOR CAPABILITY of large ships as indicated by a progressively increasing rate of speed corresponding to a progressively increasing size of ship, the ratio of displacement to power being constant.

Table No. 2, showing the SUPERIOR CAPABILITY of large ships as indicated by the progressively reduced ratio of power to displacement corresponding to a progressively increased size of ship, the speed being constant.

Table No. 3, showing the SUPERIOR CAPABILITY of large ships as indicated by the progressively increasing distance capable of being steamed without recoaling at a given speed, and with a given per-centage of the displacement appropriated to cargo.

Table No. 4, showing the SUPERIOR CAPABILITY of large ships as indicated by the reduced consumption of fuel per ton of cargo at which goods will be conveyed a given distance, without recoaling, at a given speed.

Table No. 5, showing how soon the admitted advantages which result from increased size become neutralised if on the strength of increased size alone, we undertake OBLIGATIONS which involve, on the part of the large ship, an increased rate of speed combined with an increased distance without recoaling.

The investigations above referred to, as com-

* While correcting the proof of this abstract, I learned that Dr. Franz had arrived at the conclusion that an absorption of 3.54 per cent. of the heat passing through a column of air 90 centimeters long takes place; for coloured gases he finds the absorption greater; but all colourless gases he assumes show no marked divergence from the atmosphere. —*Poggendorff's Annalen*, xciv. p. 337.

municated by me, to the Institution of Civil Engineers, and published in April, 1854, present results conclusively demonstrative of the SUPERIOR CAPABILITIES of large ships in the commercial point of view to which Mr. Cheverton now revives attention; in fact, these papers were written by me when the keel of the Great Eastern was being laid, and when scientific and speculative enthusiasm were at their height, not merely to confirm the use of, but to caution the public as to the misuse which then appeared to me to threaten the introduction of leviathan ships. If Mr. Cheverton will now prosecute these investigations, taking, as he suggests, "the simple displacement as the factor and not the power thereof," the result will, I venture to say, be the reverse of what he anticipates as respects doing justice to the commercial capabilities of the Great Eastern. But this leviathan is now afloat, ready to test the truth or fallacy of the theories that have been advanced, and although her capabilities for sea service as respects the mutual relation of displacement, power, speed, and coal have not yet been conclusively determined, it appears from the data of her passage from the Bill of Portland to Tuscar (MECHANICS' MAGAZINE, No. 42, p. 242 and 252) that with a displacement of (say) 17,500 tons, the distance, 400 nautical miles, was performed in 32 hours with a consumption of fuel at the rate of 250 tons per 24 hours, or 208.3 cwt. per hour, being at the average speed of 12½ knots per hour, with a consumption of fuel at the rate of 16.66 cwt. per knot. These data give a co-efficient of dynamic duty with reference to coal (by the formula $\frac{V^3 D}{W}$), equal to 6326.

On this assumption that the steaming speed of 12½ knots per hour requires 250 tons of coal per day; 13 " " will require 281 tons per day; 14 " " " 351 " 15 " " " 432 "

it is, however, to be hoped that the construction of the engines and boilers of the Great Eastern is such as admits of the introduction of modern improvements, whereby the consumption of fuel with reference to speed may be greatly reduced.

It may be observed that on the passage to Holyhead, the engines were not continuously worked up to their full power, and, therefore, that the capability of the ship for continuous high speed was not fully developed. This consideration, however, will not materially affect the co-efficient of dynamic duty above deduced, for the consumption of fuel per hour when working at full power would be increased in about the same proportion as the cube of the speed would be increased, and, consequently, the co-efficient of dynamic duty by the above formula remains very nearly constant at whatever speed the ship may be driven, so long as the displacement is not materially altered.

The circumstances of the passage to Holyhead do not appear to have admitted of exact data being obtained as to the rate of consumption of fuel per indicated horse-power per hour by the screw and paddle-wheel engines respectively; but it being understood that the screw engines were worked with steam partially superheated, it is probable that the consumption may not have exceeded 3½ lbs. per indicated horse-power per hour, and on this assumption the co-efficient of dynamic performance with reference to displacement and power would be about 200. This is a low co-efficient for a mercantile steam-ship, but it is about as high as I have ever known to be realized by any vessel of which the ratio of mean draught to breadth was so small as in this case of the Great Eastern, namely, only 23 to 84, or 1 to 3.65. It may be expected to improve as the vessel shall be loaded down to a deeper draught. The question involving, as it does, the merits of the type of form of the ship, is of great importance, and it is to be hoped that the Great Eastern will not be allowed to go to her moorings at Southampton without having gone through the usual ordeal of a trial by repeated runs over the measured knot in Stokes' Bay, in addition to her sea-trials for determining the present co-efficients of her

dynamic performance with reference to indicated horse-power, and of her dynamic duty with reference to her consumption of fuel.

I am, Gentlemen, yours very obediently,
CHARLES ATHERTON.

Proceedings of Societies.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

QUARTERLY MEETING, Oct. 18th, 1859.—William Fairbairn, Esq., F.R.S., &c., President, in the chair. The President announced the formation of a Mathematical and Physical Section in connexion with the Society. Dr. F. Crace Calvert presented, in the name of Mr. Arnaudon (from Turin), a paper, and samples of green colours used in painting and printing, and especially referred to two new chrome greens, one of which is a new compound, corresponding to the monohydrate of sesquioxide of chrome $\text{Cr}^2\text{O}^3\text{HO}$. The author commences in his work to point out the qualities which a good green ought to possess, in order to be suitable for painting. Then he reviews in a few words the different greens which are found at present in the market, together with the nature and properties of the same. Beginning with the history of the works already published on this subject, he next gives the description of his process for preparing his monohydrate of sesquioxide of chrome, and which consists in exposing the bichromate of potash mixed with phosphoric acid and any desoxydizing agent (for example, ammonia) for some time to the action of heat. The soluble salts are then removed by washing.

The green so prepared has not only a beautiful shade, but like that of Mr. Guignet (made by decomposing the borate of oxide of chrome by water) possesses the curious property of remaining green under the influence of artificial light. Dr. Calvert also presented some muslins printed by M. Camille Kæchlin, of Mulhouse, with fuchsine, a product obtained from the aniline of coal tar. This colour was very remarkable from the exquisite bloom of the pink shade obtained when fixed with albumen.

The following extract of a letter received from Professor W. Thomson, F.R.S., Honorary Member of the Society, &c., was read by Dr. Joule.

"I have a very simple 'domestic' apparatus by which I can observe atmospheric electricity in an easy way. It consists merely of an insulated can of water to set on a table or window-sill inside, and discharge by a small pipe through a fine nozzle two or three feet from the wall. With only about ten inches head of water and a discharge so slow as to give no trouble in replenishing the can with water, the atmospheric effect is collected so quickly that any difference of potentials between the insulated conductor and the air at the place where the stream from the nozzle breaks into drops is done away with in my apparatus at the rate of five per cent. per half second, or even faster. Hence a very moderate degree of insulation is sensibly as good as perfect, so far as observing the atmospheric effect is concerned. It is easy, by my plan of drying the atmosphere round the insulating stems by means of pumice-stone moistened with sulphuric acid, to insure a degree of insulation in all weathers, by which not more than five per cent. per minute will be lost by it from the atmospheric apparatus at any time. A little attention to keep the outer part of the conductor clear of spider lines is necessary. The apparatus I employed at Invercloy stood on a table beside a window on the second floor, which was kept open about an inch to let the discharging tube project out without coming in contact with the frame. The nozzle was only about two feet and a half from the wall, and nearly on a level with the window-sill. The divided ring electrometer stood on the table beside it, and acted in a very satisfactory way (as I had supplied it with a Leyden phial consisting of a common thin white glass shade, which insulated remarkably well, instead of the German

glass jar—the second of the kind which I had tried, and which would not hold its charge for half a day). I found from 13½ to 14° of torsion required to bring the index to zero when urged aside by the electromotive force of ten zinc-copper water-cells. The Leyden phial held so well, that the sensibility of the electrometer measured in that way did not fall more than from 13½ to 14° in three days. The atmospheric effect ranged from 30° to above 420° during the four days which I had to test it—that is to say, the electromotive force per foot of air measured horizontally from the side of the house was from nine to one hundred and twenty-six zinc copper water-cells. The weather was almost perfectly settled, either calm, or with slight east wind, and in general an easterly haze in the air. The electrometer twice within half an hour went above 420°, there being at the time a fresh temporary breeze from the east. What I had previously observed regarding the effect of east wind was amply confirmed. Invariably the electrometer showed very high positive in fine weather, before and during east wind. It generally rose very much, shortly before a slight puff of wind from that quarter, and continued high till the breeze would begin to abate. I never once observed the electrometer going up unusually high during fair weather without east wind following immediately. One evening in August I did not perceive the east wind at all, when warned by the electrometer to expect it; but I took the precaution of bringing my boat up to a safe part of the beach, and immediately found by waves coming in that the east wind must be blowing a short distance out at sea, although it did not get so far as the shore. I made a slight commencement of the *electro-geodesy* which I pointed out as desirable at the British Association, and in the course of two days, namely, October 3rd and 4th, got some very decided results. Macfarlane, and one of my former laboratory and Agamemnon assistants, Russel, came down to Arran for the purpose. Mr. Russel and I went up Goatfell on the 3rd inst. with the portable electrometer and made observations, while Mr. Macfarlane remained at Invercloy, constantly observing and recording the indications of the house electrometer. On the 4th inst. the same process was continued to observe simultaneously at the house and at one or other of several stations on the way up Goatfell. I have not yet reduced all the observations, but I see enough to leave no doubt whatever but that cloudless masses of air at no great distance from the earth, certainly not more than a mile or two, influence the electrometer largely by electricity which they carry. This I conclude because I find no constancy in the relation between the simultaneous electrometric indications at the different stations. Between the house and the nearest station the relative variation was least. Between the house and a station about half way up Goatfell, at a distance estimated at two miles and a half in a right line, the number expressing the ratio varied from about 113 to 360 in the course of about three hours. On two different mornings the ratio of house to a station about sixty yards distant on the road beside the sea was 97 and 96 respectively. On the afternoon of the 4th inst., during a fresh temporary breeze of east wind, blowing up a little spray as far as the road station, most of which would fall short of the house, the ratio was 108 in favour of the house electrometer—both standing at the time very high—the house about 350°. I have no doubt but that this was owing to the negative electricity carried by the spray from the sea, which would diminish relatively the indications of the road electrometer."

A paper was read by Mr. Hopkins, entitled "On Irregularities in the Winter Temperature of the British Islands."

The Chairman of the Great Eastern Company has forwarded a telegram to J. R. Stebbing, Esq., to the effect that the great ship sailed from Holyhead on Wednesday at 12.30 for Southampton, where she may be expected this evening (Friday).

NEWINGTON'S APPARATUS FOR DISTRIBUTING SEEDS AND MANURE.

DR. SAMUEL NEWINGTON, of Ridgway Ticehurst Sussex, has just completed a patent for the apparatus for distributing seeds and manure represented in the annexed engraving. This apparatus is applicable for distributing guano, lime, and all kinds of dry pulverized manure, and for distributing corn, grass, and other like seeds broadcast. *a* is the hopper, to the upper part of which the shafts *b b* are attached. The side *a'* of the hopper turns at its upper edge on the hinge *c*, so that the lowest edge of the side *a'* can be moved to or from the lower part of the side *a''*; to the lower part of the moveable side *a'* are bolted projecting pieces *d d*. A vibratory motion is communicated to the side *a'* by projecting blades, or teeth, *e*, on the axis *f*. On this axis there are two ratchet wheels, into which pawls (turning on pins fixed to the bosses of the wheels *g*) are pressed by means of springs, which are also fixed to the bosses of the wheels, so that the axis *f* is only caused to rotate when the machine is drawn forwards; the rotation of the axis *f* causes the projecting blades *e* upon it to strike in succession against the projecting pieces *d* fixed to the moveable side *a'* of the hopper, and so give to it a vibratory motion. The moving the side *a'* towards and away from the side *a''* allows the seeds or manure to fall on to the blades *e* on the axis *f*, and as the axis rotates, the seeds or manure fall on to the board *l*, and the vibratory motion of the side *a'* also keeps the manure in the hopper agitated. The board *l* at one edge turns on the hinge *m*, and a vibratory motion is communicated to this board by its being connected by the chains *n* to the vibrating side *a'* of the hopper, and the seed or manure will thus be shaken off this board on to the land. The hinge *c*, upon which the moveable side *a'* turns, can be raised or lowered by screwing or unscrewing the nut *c'*, and the distance between the end of the side *a'* and the lower part of the side *a''* can thus be varied, and by this means the amount of seed or manure distributed on to the land can be varied. When it is desired to stop the seed or manure from descending from the hopper, the end of the side *a'* can be drawn against the side *a''* by depressing the long arm of the lever *o*. A greater quantity of seed or manure may be allowed to fall from the hopper by turning the pieces *d d*, so that they are not acted on by the teeth *e* on the axis *f*; the teeth *e* will then strike against the end of the moveable side *a'* of the hopper. A still greater amount of seed or manure may be allowed to fall from the hopper by raising the side *a''* of the hopper away from the blades on the axis *f*; for this purpose the side *a''* is carried by hinges which can be raised or lowered in a similar manner to the side *a'*.

In arranging the apparatus for distributing seeds or manure in furrows, a box containing the

ALLAN'S APPARATUS FOR RETARDING AND STOPPING RAILWAY TRAINS.

seed or manure is placed inside the hopper, and attached to the moveable side *a'*, and holes are formed through the side *a'* near its lowest edge, and through the box containing the seed, and as the machine moves forwards the seed or manure is shaken out through these holes into funnels carried from the fixed ends of the hopper, and is by them guided into the furrows, or the seed or manure may fall on the platform *l*, and be guided into the furrows by pieces of wood screwed on the board at intervals. The holes in the side *a'* and in the box are kept clear by means of wires; these wires are fixed to a bar passing along the upper part of the hopper, and pass down through the seed or manure to the holes, and as the side *a'* is moved to and fro, the wires enter and leave the holes, and so keep the holes free. Proper apparatus for forming the furrows may be attached to the front of the machine.

AN IMPROVED METHOD OF RETARDING AND STOPPING RAILWAY TRAINS.

By ALEXANDER ALLAN, Engineer, Perth.

In the prevention of collisions, and their consequently serious results, a few seconds are most valuable: the danger also is, in most cases, first seen by the man in charge of the engine. The object of these improvements is, therefore, to give the driver increased power of controlling the speed of, and in stopping the trains; and for this purpose, and in order that the whole break power of any train may be brought into requisition in the shortest possible time, it is recommended that, in addition to the apparatus to be hereinafter described, a cord shall be placed within convenient reach of the men on the engine, communicating with a bell fitted up in the first break-van, by which means the guard may be apprised of his assistance being required at the van-breaks.

The improvements consist of two distinct parts. 1st. By inserting a throttle or other valve in the exhaust-pipe of the engine at *A*, so that by means of a connection *B* the driver can fully or partially close the valve *A*. By the table of experiments appended, it will be seen, that by the closing of this valve (the regulator being at the same time open), a retarding force is opposed to the engine of equal power with the tender breaks, and for all ordinary stoppages this can be used to bring the train almost to a dead stand—the tender break being applied only for say the last dozen yards, thus effecting a great saving in the permanent way, tender-tyres, and break-blocks.

The second part of the improvements consists of a steam break to work in connection with the above valve in cases of great danger. The steam is taken from the exhaust-pipe by means of the pipe *C* which is supplied by a stop-cock or valve

F, worked from the foot-plate by the connection *D*, which being separate from the connection *B*, it will be seen that one or both of the retarding forces may be used at pleasure. The steam from the pipe *C* passes to cylinder *E*, actuating the piston *H* and levers *K*, &c., and break-blocks *N*, which may be applied to all the wheels if desired, but by preference they are shown attached to the leading and trailing wheels only of passenger engines. On the steam being released, the weight of piston, rods, and levers will free the break-blocks from the wheels.

By partly closing (more or less) the throttle-valve, trains may be controlled when passing down steep inclines to any desired speed, leaving in reserve (in the case of heavy goods trains especially) a great surplus of break-power to bring the train to a stand quickly on any incline—namely, that of the steam-break herein described, and also that of the tender and van-breaks. In illustration of this, an experiment, not included in the table, resulted as follows:—On an incline of five miles, the gradients averaging 1 in 80 (descending), and with a gross load, estimated at 200 to 210 tons, the throttle-valve alone controlled the train from a starting speed of thirty miles per hour to fifteen miles per hour over the whole distance.

The partial closing of the valve may also be made to prevent violent slipping, as the wheels will only revolve in proportion (*i.e.*, the traction will only be equivalent) to the quantity of steam allowed to escape from the exhaust-pipe, and this may be regulated to any extent by the valve, which can be worked with greater ease and nicety than the regulator.

With regard to reversal, it is known to be extremely difficult, if not impossible, to reverse an engine at speed, but it will be seen that, with full steam on the pistons, the closing of the throttle-valve, which is not effected by speed, produces a result quite equal to that of reversal, whilst reversal itself is facilitated by a greater equalization of the pressure on both sides of the valves, and an increased break-power is obtained (see Table) without the usual objectionable results of reversing the engine whilst in motion.

The combined effect of these appliances may further be shortly stated to be,—

- 1st. By the throttle-valve alone a power is exerted equal to that of the tender breaks.
- 2nd. By use of the tender-breaks in combination with the above, a doubling of this power is obtained.
- 3rd. By using the engines' steam break-blocks, the throttle valve, and the tender breaks together, a retarding power equal to triple that of the tender breaks alone is brought out.
- 4th. In addition to the above, by reversing,

this retarding power is still further increased, and

5th. By the recommended communication from the engine to the van, used in combination with the whole, a power of stoppage is obtained, which has not hitherto been equalled, and within much less time. This last is the most important element, as all necessary manipulations can be gone through in one or two seconds after their requirement being noticed.

TABLE.

Abstract of experiments with a gross load of 85 tons, made up as under:—

Engine	18 tons.	} 85 tons. Weather calm; rails dry.
Tender	12 "	
11 Empty carriages. 55 "		

Gradients.—The first $\frac{1}{4}$ mile from the post at which the break-power was applied was level. The next $\frac{1}{4}$ mile further, $\frac{1}{8}$ rising gradient. In every case, the retarding force was applied at the same mile-post on the same line of rails. The carriage-breaks were not applied in any case.

Number.	Seconds to $\frac{1}{4}$ mile.	Miles per hour.	Seconds to stop in.	Distance run, yards.	Class of Break, and Remarks.
1	25	36	156	1432	No breaks applied.
2	25	36	80	800	Throttle valve only used. Valve leaky did not bring the train to a dead stand. Speed was very slow for the last $\frac{1}{4}$ th of a mile.
3	25	36	66	713	Tender break only.
4	24	36 $\frac{1}{2}$	63	710	Throttle valve closed, and engine reversed.
5	25	36	50	460	Throttle valve closed, engine reversed, and tender break used.
6	25	36	55	450	Throttle valve closed, and tender break used.
7	25	36	50	400	Throttle valve closed, and engine steam-break applied.
8	25	36	30	275	Throttle valve closed; engine steam-break and tender-break applied.
9	25	36	23	220	Throttle valve closed; engine reversed; steam-break and tender-break used.

NOTE.—The results as per table were obtained from an engine with the throttle-valve and steam-break fitted up only in a temporary manner. With the apparatus more perfectly applied better results would necessarily be obtained.

GARFORTH'S IMPROVEMENTS IN STEAM PISTONS.

Messrs. W. and J. Garforth, of Dunkinfield, Chester, have just patented an invention designed to obtain a sufficiently tight packing between the piston and cylinder to ensure its being steam-tight, without the necessity of exerting more pressure, and causing more friction between the piston and cylinder than is absolutely required to effect a steam-tight packing. The improvement in the piston for effecting the desired purpose consists in an outer ring or rings of ordinary construction, which are to be expanded against the cylinder by an internal V ring made in sections, each of such sections being provided with a small piston or pistons, one end of which acts upon the V ring, and the other receives the direct pressure of steam which is supplied and conveyed to an annular

space in the interior of the piston by a steam pipe, which rises and descends through a stuffing-box in the cylinder cover with the action of the piston. In this arrangement it will be evident, that by so applying the action of steam to the expanding V piston ring, the pressure of such steam, and, consequently, the piston packing, may be so regulated as to admit of a pressure being exerted, sufficient only to maintain the piston packing in steam-tight contact with the interior of the cylinder. The accompanying engraving is a vertical sectional view of a cylinder and piston, to which the improved steam-tight packing is shown applied, clearing illustrating the method of applying the steam to the packing ring by means of the pistons and V wedges. $\alpha \alpha$ is the cylinder, and b the piston; $c c$ being the packing rings, and d the annular V wedges which force the packing rings into contact with the interior of the cylinder, by means of the small horizontal pistons $e e$, against which the steam exerts pressure; the steam being supplied to the annular cavity f behind the small pistons $e e$ by means of the pipe g , which rises and falls with the piston b through the stuffing-box in the cylinder cover, and receives the steam from the chamber h which is supplied by the steam pipe i . Thus it will readily be seen, that the pressure of the piston packing against the cylinder may be regulated according to the amount and pressure of steam supplied to the annular cavity or chamber f .

THE SCREW AND THE PROPELLER: THEIR PROPERTIES, THEIR INVENTORS, AND THEIR IMITATORS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—It is now thirty years since the writer of these remarks first became acquainted with the propelling properties of the screw, during which period, wishing well to the interests of its poor and ingenious inventor, he has watched in confidence its progress of improvement as a marine engine with much disappointment, yet with no common interest. The little history of this much coveted instrument of jealousy is simply this:—When eight years of age, George Blencowe, then living at Barnet, seeing his mother's servant trundling a mop, cut a hedge stake out of his father's garden, and with a bit of paling crossed and a few twists of a cord round its shaft as it lay transversely in a punt with two sticks across to rest its spindle upon at its stern, spun it as boys do a water cutter made of a round bit of tin or a penny piece with a hole and string through it, propelling its little freight across a duck-pond as true as an arrow, and with a celerity, to his astonishment, equalled only by the ducks scudding before it, to the great delight of the old people looking on behind the lattice at the energy and ingenuity of their little Georgy. It so happened, as the boy grew up, that he made friends of a favourite companion of his father's, an excellent mechanic and clock-maker named Shorter. To him George opened his heart, his friend the while exhibiting to his pupil the fly-wheel of a smoke-jack, from which, after depriving it of four of its fans, they constructed after a rough fashion the following screw in a right line with its spindle, with the original bit of paling at the end of it:—

This, it must be admitted, was not a bad be-

ginning, but still it didn't do as well as the primitive and original contrivance of the mere mop-stick and paling. Mother-wit, which is seldom at a loss at a pinch, soon suggested the separation of their beloved idea, and out of the united fertility of their contrivance, sprung their next essay out of the bottom of an old saucepan, long having done duty as a stop-gap to the cocks and hens in the back garden. Of course the family shears in the shape of sundry scissors came in for their share of the anticipated benefit of the dear boy's genius for mechanics, which Mr. Shorter very unceremoniously applied to the purpose of turning out specimens of propellers as numerous as they were omni-genous. Even the garden shears with which the old gentleman had used to cut out the peacocks for half-a-century in the forecourt were embedded in the stump of an old tree as a vice, and did duty in paring and pruning bits of tin till they became, with the assistance of a string and a pin, as geometrically correct as a pewter platter, and flourished awhile at one side of his screw stick with a shoulder of mutton blade-bone at the other, as under, till the junction of bone and tin relapsed into a divorce by sheer practical exhaustion:—

From this severance of their profound idea sprung another device worthy of Archimedes himself, the bit of tin having the preference of their choice, and the blade-bone giving way to be the more useful, as the sequel will show, for the future prospects of the youthful and enterprising mechanical aspirants.

We now leave awhile incipient mechanism and disappointments for the broader field of invention, as it opens to one's view in the varied lustre of its beautiful phases as they flit before genius. It occurred about the year 1832, during the interval of a little adult schooling and experience, that the old trial of the screw, for the sake of practice, as an engineer, the boy, now a man, ought to revive; and under the bettered circumstances of George's acquired store of knowledge, being now master of the first principles of geometry, his resolution was taken to prosecute and perfect the old invention. Accordingly, the energies of the old people took fire at George's genius, and burnt briskly as they set to work to exhume the dry bones of his early labours out of the back shed, where they had rested so long undisturbed, for the reflective benefit of the bats and owls that had looked upon them with a jealous eye as something sacred to their snug Arcadia. Esquire Hearty, who had kindly consented to the young man's application to try his skill as a mechanic upon his lake, promoted his young neighbour's aspirations of industry, it being his pride to love and be beloved, and to share in the happiness of all within his social circle; and though George at this time fought hard against fortune, a kind friend or two were not wanting in addition to furnish him with a few tools and necessities to complete what he had begun when a stripling, with so much success as an engineer, at the end of a hedge stake or broom stick. Of course for this primitive pediment of science was substituted

a spindle as bright and sparkling, as his father said, as a lady's eyesight. And for the mutton bone and top of the old tin saucepan was substituted a circular piece of block tin, cut through and fashioned as shown.

which when transversely twisted, thus,

and fixed on its axle, gave this next transfiguration of its economy:—

This prodigious effort of poor George's, though considered the best screw of the day, succeeded by Ericsson's which much resembled it, and the Smith's, Brown's, Jones', and Robinson's imitations of them being somewhat overlaid with science, inasmuch that it was not calculated to give motion until the completion of its first revolution, as well as to sustain the pressure of the ship's way at fifteen knots an hour, (which is calculated to be six tons on the point opposed to its resistance supposing its diameter twelve feet,) was soon set aside, as all screws ultimately will be, for the propeller, which George at first, as has been shown, started with. So without much ado, the old idea of the mop-stick came into vogue again, and forthwith grew out of it the following invention, the mutton bone, in a very great degree, serving as the pattern in the shape of a fan at an angle at 45° of its axial motion:—

After a world of hard labour, as he termed it, George, after boxing the compass of all the angles under the sun, and making the machine describe as many circles in an hour as gyrations are performed on a windy day, as the gardener said, by a cherry clapper, finding the principle of its action the correct one, at once sought out for the means to protect it in a patent, then requiring some hundreds of pounds to complete it. Of course, like many as good or better men before him under like circumstances, George's little castles in the air came to the ground for his want of capital, crushing his hopes in their fall as he saw rise from their ashes a hundred of his wealthy imitators, now many of them enjoying the proceeds and premiums of the wreck of the genius of the screw's sole inventor.

It is rather a remarkable feature in the imitations of the screws of George Blencowe, from the first which he had permission to try on the lake of Captain Trotter's park at Totteridge, in Hertfordshire, to that which he had perfected in 1832, now used with a trifling deviation from its original by the Great Eastern, none seem to have got the correct angle of 45° of their axial motion. And though science is indebted to Sir Howard Douglas for his animadversions on many similar faulty inventions, yet is but little additional knowledge to be gleaned about the screw in his little work on Naval Warfare,* replete as it is with great modesty and ability. There is one remark, however, about the disadvantageous position of the screw under the ship's counter deserving the greatest attention, not the less for its ever having been a point in debate amongst scientific men from its first invention, than for the stubborn perseverance in the present practice of its faulty situation. "From the position of the screw in an aperture close under the

ship counter," as Sir Howard very justly remarks, "the water which is divided by the body of the ship subsequently flows obliquely towards the screw; and again, the water, after being pressed by the screw, is broken by the stern-post and rudder, where being arrested, part of it is forced forward in the direction of the ship's motion." Doubtless, this is a serious objection to the fair-play of the screw's action; and if the pressure of motion is as the cube of the screw's diameter, as much power of propulsion is lost as that back pressure retards it, particularly as the gyrations of an eddying volume of water act impulsively upon its revolutions. "Another objection to the screw in its present position of the vessel," continues Sir Howard, "is, that the shake of the screw, and the consequent injury to the stern of the ship, are caused by the sudden and violent reactions of the disturbed water in that place against the blades of the screw as they enter and emerge from thence." But the remedy proposed in rounding the fans of the screw, or whether they be angular or semicircular, does not appear fairly to meet the objection, since the stroke of its diameter must determine its force. To give this ingenious invention fair-play surely it is necessary to disentangle it of all such impediments (as described by Sir Howard). If at the stern of a vessel the plunging against the screw of the eddy and the disturbed current of the ship's way distracts its motion, surely there is a remedy at hand in fitting it to the bows of a ship before or after its cut-water, where the undisturbed action of the fluid's equal pressure would give a steadiness of motion irrespective of such fatal objections.

Whilst passing in review the subject of the screw, or more properly propeller (since it has no property in common with the former in the water than a figure of 8 has above it when cut out by a skater), a further and equally interesting anecdote of its invention, more recently than that just described, may not prove uninteresting to those who lean rather to sympathy with original genius than to a worship of the wealth accumulated by its practical application. To Mr. Farquhar, of Tower Hill, the eminent chronometer maker, be then the honour due in his own words, of the revival of its discovery. "Sir," said the old gentleman, after hearing the errand, and measuring his inquirer's mental stature under the deep and thoughtful brows of a northern head that had won its mechanical immortality—"Sir," continued he, "your introduction by my friend is your welcome. Sit down, Sir. Well, now you must know, Sir, taking the morning air as I usually did thirty years since over the drawbridge of the London Docks, my attention was arrested by a youth about twelve years of age propelling, or sculling, as it is called, a boat by its stern in a manner so unusual as to excite my unbounded curiosity, and to venture in me a thought of its transference to circular motion. Ever delighted at improvement—for our countrymen never throw a chance of advantage away, as you southern good-humouredly say, honestly acquired—I was at once delighted and instructed, and the lad and I were the best friends in the world long after; he for the value to me of his skiff, and I to him of the means of earning an honest penny. It was no little trial, to one like myself, of six feet stature, unable to swim, and bury withal, as you may suppose, Sir, when the tide at times ran wildly, to adjourn with him to the deep-water of the Lea, there to abide the rocking to and fro of his little cockle-shell, not more than double my length, and of such slender proportions as to require my holding on its gunwales with a tenacity and grip with which you know, Sir, my countrymen, in common with all, ever hold their own with. However, giving the lad a fair price for his lesson, my best wits, after putting together and pulling to pieces as many bits of tin, models of little ships, some with holes at their sterns, and others with wells in their middles, as would fill a garret, and coupling what I had learnt of the skiff's motion with that of a fairy wheel, which as children we all have delighted in during windy weather, as it skims along the ground like the

flue of the heather, made out in the rough the following models:—

A the back of an oar blade;
B the front ditto;
C a fairy wheel.

Now you see, Sir," continued the animated old gentleman, "by reducing the fans to a pair, twisting them inversely at an angle of 45° of each other, and inserting them at the end of a split stick, thus,

and then through a tube to my clockwork in the boat, my screw as my heart seemed to respond to its motion spun away my model after the following fashion, from one side to the other of the creek, as true as a water-rat":—

A public exhibition of this taking place, of course the same fate befell it as its predecessor by Blencowe, as the following statement will exhibit, printed about the time of the award of a premium for the screw's discovery to certain capitalists, and to the patentee of a very similar screw, indeed, by a gentleman:—

"Statement of William Farquhar, the real Inceptor of the Universal Under-water Propeller, claimed and patented by Lieutenant Carpenter.

"If the government of this country, of whatever party, had not shown invariable disposition to do justice to individuals, however obscure, who had a clear and dispassionate case to present, the undersigned would hesitate to solicit attention to this statement. If a right could cease to be a right, because he who had it lacked means to bring it under the notice of those influential to recognise it, the writer of this statement would despair of the justice he now seeks.

"In 1828 (so far back as this date) I, the undersigned, William Farquhar, was in the employ of Mr. Grant Preston, a relative, a well-known inventor, to whom the navy owes the Ship Deck Lights still in use. The constant talk of naval improvements going on in that society first turned my mind to inventions, of which in my time I have perfected several. Standing one day in the London Docks on one of the swing-bridges, I noticed under me a man scudding a boat, when it instantly occurred to me that the oblique action of the oar could be produced by wheel-work. I went home, and found three persons (two of whom are now living) and proposed the thing to them.

*"On Naval Warfare," p. 37. Murray, London, 1858.

They were all persons that had considerable influence in such matters; but, as it frequently happens in these cases, my proposition was received so coldly as to deter me from prosecuting the design I had formed—the design now understood to be Lieutenant Carpenter's. It was not until 1833-4 that circumstances induced me to recur to the aforesaid idea, and then an event occurred that gave a clear proof of its superiority to any other plan. At that time I was employed to make a piece of machinery for driving a model boat, the patent of Mr. W. Hale. The party for whom it was made disagreed with Mr. Hale, and a law-suit ensued; when I, to show him who lost his money in the matter that he had lost nothing, made a model of my aforesaid invention, which answered beyond my expectation. From that time up to 1839, I kept showing it to everybody I thought capable of understanding it. Many nautical men in the navy, and engineers, and practical workmen saw it, many of whom (some have since deceased) I am ready to produce in proof thereof. As, however, I had no means of applying my invention, I was naturally disheartened. At the end of 1838, or early in 1839, I was invited by the captain of a large steamer to inspect a model of a similar invention, exhibited in a public room in Gracechurch-street. Here I first met Lieutenant Carpenter, who had himself a model of a gun brig with him, which Admiral Sir Arthur Farquhar (at that time in the room) had declared utterly fruitless. Lieutenant Carpenter was disheartened, and took his model to a side table. I followed him, and pointed out to him exactly what was wanted; and my idea of the Universal Underwater Propeller* was exactly what he shortly after patented, and nearly in the very words I had used: though at this conversation he said, 'the idea (the plan I described to him) had never entered his mind;' these were his exact words. I afterwards showed my invention at the Polytechnic by the special desire of Admiral Sir Arthur Farquhar: and on that occasion I established my priority to the invention in Lieutenant Carpenter's presence. Persons, at that time when he took his patent, commonly remarked that the invention was mine. I have had no means adequate to the establishment of my right to it, but I have never ceased publicly and privately to assert my claim to it; and now that Government are about to reward the actual inventor, I respectfully pray for a committee of inquiry into the real origin of the aforesaid invention, and to be examined with my witnesses upon it. I offered my invention to the Admiralty before ever meeting Lieutenant Carpenter.

"Fully aware that few things are more perplexing and disagreeable than to decide among rival claims of inventors—positive, dogmatic, impatient, antagonistic, often urging their claims with the heat of a monomania—the aversion to listen to them I know is very great, and I am not very sanguine of success on this account. Still somebody, after all, is the real inventor in all cases, and justice should be done to him for the sake of scientific progress. In this belief I beg permission to submit my statement to your friendly consideration."

"WILLIAM FARQUHAR,

"10 King-street, Tower-hill, London."

"May, 1855."

"COPY OF PETITION BY THE AUTHOR OF THE STATEMENT."

"To the Honourable the Commons of Great Britain in Parliament assembled."

"The humble petition of William Farquhar, of No. 10 King-street, Tower-hill, London, sheweth:—

"That your petitioner was the inventor of the propeller used in the navy and other vessels for underwater propulsion, of which propeller your petitioner made a working model in 1834. That your petitioner loved the invention during a period of five years, and offered it to many persons whom he thought capable of appreciating its value, but with little success.

"At length your petitioner having met in a public room in Gracechurch-street Lieutenant Carpenter, your petitioner described his invention to him. The said Lieutenant Carpenter took out a patent for the same invention a few weeks afterwards. These facts your petitioner can clearly establish, and he earnestly and respectfully prays your honourable house to institute an inquiry into the real origin of the aforesaid invention, and cause your petitioner to be examined thereupon.

"And your petitioner will ever pray."

Perhaps the following idea of the fans set at angles of 45° of each other, and coming as nearly

* "Inventions of this nature are properly called 'Screw spellers,' but as no part of a screw is employed in the useful invention adopted in the Navy, I adhere to my final plan, which is nearest the mechanical truth."

as possible to the original models, might serve as a hint for improvement, particularly if it can cause the fluid upon the screw's axis, which the present one in use is far from effecting.

But its proper place, let it be borne in mind, as before hinted, is forward, as sailors say; for who would fix the sails behind instead of before the windmill?

With such facts before us, can it be surprising, Gentlemen, that men of genius, without the means of promoting their inventions, are so much preyed upon by capitalists, dividing amongst them at least the £15,000 awarded by Government? Whatever may be said to the contrary by shrewd calculators looking on rags as they cull its fruits for their own advantage, there can be no question that science is ever the sufferer, as the scores of discarded screws will prove, by such conduct, as well as the inventors. And there is no mistake so fatal to the advancement of genius, as that made when premiums without inquiry are injudiciously awarded (as in this case of the two gentlemen referred to), to bustling unscrupulous men of business, having the ear of State interest, and eminently successful by assurance.

I have the honour to be, Gentlemen,

Your obedient servant,

W. DE ST. CROIX.

Grove-end, Highgate, 15th Oct., 1859.

IRON SHIPBUILDING.

A MANCHESTER correspondent writes the following letter:—Among the many and mighty inventions and adaptations which have contributed to make this country and this age famous, a conspicuous place must be given to the application of iron to shipbuilding. Without it England's mercantile marine could scarcely have kept pace with the marvellous growth of her commerce, and oceanic steam navigation would yet have been in its infancy. Even Brunel's genius would have quailed in attempting the construction of the Great Ship in any other material; and it is scarcely too much to say that the abundance and richness of the ferruginous ores which are found in this island, and the facilities for their reduction placed to our hands by nature, compelled our naval constructors to direct their attention to the use of manufactured iron in building vessels.

The iron ship, when well built, is indeed stronger, safer, and more durable than any other and yet if we search the records of those disasters to which all seagoing ships are exposed it will be found that the most destructive and appalling have occurred in iron bottoms. I need only call to mind the wreck of the Birkenhead, which will find a place in history as the scene where the disciplined bravery and devotion of our soldiers were nowhere more conspicuously displayed, and that awful and heartrending catastrophe which within the last few days has carried sorrow and anguish into hundreds of homes. Yea, while the hearts of relatives are yet bleeding, and the public is stunned with the immensity and suddenness of its loss; while many would try to bury their grief in oblivion, and others would prefer to contemplate in silence such an illustration of the mysterious end of Providence, I conceive that the lessons which the loss of the Royal Charter is calculated to afford ought not to be overlooked, and that the causes of a wreck so sudden and so complete should be most promptly and searchingly investigated.

I would, therefore, very earnestly and very

prominently bring under the notice of your readers certain general features and practices in the construction of iron vessels which in my opinion are in the last degree dangerous and reprehensible. It would seem to commend itself to the common sense of every man that in building an iron sailing or steamship which is to be subjected to all the strains and buffetings of tempest-tossed seas, which will be freighted with hundreds of human beings and the most precious cargoes, and which must run the risks of collisions and strandings, none other than the very best and strongest materials should be employed. The toughest iron, the best seasoned spars, and the stoutest planks and ropes should alone find places in such a venture. But in our ordinary every-day practice is this the case? Is not any kind of iron thought good enough to build a ship with? What is the meaning of "boat plates" being the lowest priced in any ironmaker's list? If we pay £25 or £30 a ton for the plates of which a locomotive boiler is made, why should we give only £8 10s. or £9 per ton for those of which a ship is built? If safety can only be bought at the high price in the one case, are we not courting disaster with the low price in the other? Who will draw the fine line of distinction in moral responsibility between the directors of a railway company who should take your fare, place you in a comfortable first-class carriage, and drive you at 40 miles an hour over a viaduct which was miserably insecure, and the owners of vessels who send passengers to sea in ships sheathed with plates which are as brittle as glass? The only answer to this question in the way of excuse is, I fear, that most men are really and truly ignorant of the facts. In the eyes of the merchant in London or Liverpool who orders the building of a ship, iron is iron. He probably does not know that in this material there are as many shades of quality as there are in the wines or fruits which all bear one common name; and yet I am within the mark when I say that he might by paying £2 or £3 per ton increased price upon the plates forming the outward sheathing of his ship immensely increase the vessel's strength and durability.

With good well-worked plates, where the fibre of the iron is ductile and tenacious, and where these plates are well and judiciously fastened together, no vessel, even if wrecked in such a gale as that of last Tuesday, would break to pieces so suddenly and so utterly as the Royal Charter seems to have done.

But built of the "boat plates" of the present day God help the human freight of the ship that strikes upon the rocky shore!

I would therefore advise shipowners when contracting for new vessels, instead of being satisfied with a specification which provides good ordinary "boat plates" to be used, and which are, in fact, about the most rubbishy quality of iron which is made, to insist that the sheathing should all be of best, or double-worked quality. In a vessel of 1,000 tons it would not increase the cost 500*l.*, and the value is gained in the greater strength and durability of the ship, and to say nothing of the lives that it may possibly save.

Further, I would caution all well-disposed shipowners to look with great suspicion upon the cheap offers which are constantly laid before them as temptations to order ships. To any one conversant with a ship's value, what other construction can be put upon a contract for a vessel of 1,000 tons with the most expensive outfit, for 13*l.*, or 13*l.* 10*s.*, or even 14*l.* per ton measurement ready for sea than that the builder means to employ bad materials and scamp his work? He begins upon such an order with a determination either to cheat his customer or cheat his creditors. But such vessels are built on the Clyde, the Tyne, and elsewhere, and I maintain that the shipowner in buying them shares with the builder the moral responsibility of a great guiltiness, for they are deliberately launched and freighted to go to the bottom.

I am, &c.,

Your faithful servant,

AMCRA.

Manchester, Oct. 31.

IRON STEAM-SHIPS.

THE following remarks on iron steam-ships, by Mr. W. Litchfield, deserve consideration:—"The awful catastrophe of the loss of the Royal Charter, and her speedy breaking up on the rocks in Molfre Bay, has recalled to my mind certain discoveries which have of late been made by the officials of Her Majesty's Dockyard at Portsmouth in relation to iron vessels, which I think cannot be too widely known, and may possibly have some connection with the speedy breaking up of the Royal Charter. Iron steam-vessels have arrived home from foreign stations to a certain extent leaky, and after being paid off and cleared out have been taken in hand for the necessary repairs. On the insides of the vessel's plates being examined it has invariably been found that the whole of the rivet herds, where the wash of the bilge-water reached, had been worn off as cleanly as if cut by a hammer and chisel. This has led to a composition or cement being used over the surface of the plates of sufficient thickness to raise the surface of the plate to an equality with the head of the rivet, and in some cases bricks have been laid on the top of this cement, thus presenting a smooth surface to the wash of the bilge-water, and preventing its action on the heads of the rivets. In every case where this has been tried, the results have been perfectly successful, the heads of the rivets, after considerable service, being as sound as the first day they were made. On the contrary, where the rivets have not been protected, but left to the action of the water and grit, in every case have the heads of the rivets been destroyed, and with nothing to prevent their falling out the first severe strain the vessel should meet with at sea. Her Majesty's troop-ship *Magara*, now in the steam-basin at Portsmouth, and lately returned home from foreign service, is an illustration of what I have stated, and thousands of rivets are now in her bottom which can be knocked out by a common punch from the inside. The plates of the Royal Charter may have been protected in a manner that would preserve their fastenings, or they may not have been. The fact could very easily be ascertained, and its importance will, I trust, be sufficient excuse for my addressing you on the subject."

STEAM TOWAGE ON CANALS.

THE following letter relates to Mr. Spence's paper on Robertson's Chain Propeller published in our last number:—

Sir,—In your *Journal* (of the Society of Arts) of the 30th ult. is an article describing an invention by Mr. W. Robertson, of Strangeways, Manchester for the traction of barges on canals, and an experiment said to have been made on the Bridgewater Canal. The paragraph states that various attempts have been made to employ upon canals steam-tugs propelled by paddles or screws, in place of traction by horses, and says the objection against them is always the same—that the waves created by the propelling surface injure the banks, &c. It then proceeds to describe the invention, and concludes by saying that the experiments proved highly satisfactory.

In the first place, the experiment can hardly be considered satisfactory when there is a loss of 25 per cent. in drawing an empty canal-boat: but the chief objection is, that the difficulty of steam traction for canals is not fairly stated. That the waves created by the propelling surfaces injure the banks, when the screw is used, is simply untrue. The injury to the banks is caused by the increased speed of the vessels, which, in a narrow canal, lowers the water when each boat is passing about eighteen inches, and the sudden return of this does the injury complained of. When the speed is less than four miles an hour it is not observable, but beyond this the injurious effect is very apparent, without any perceptible wave from the action of the screw.

Some years since an experiment was made on the canal between Wigan and Liverpool, in the presence of several of the directors of the canal

and large coal-owners who wished to economise the carriage of coals. A long, narrow screw-steamer was employed, and it drew a long train of laden coal-barges, diminishing the number at intervals. It was found that, whilst the amount of load made comparatively little difference in the power of traction, the injury to the banks was solely caused by the rate of speed, which it was not safe to increase beyond a horse's walk. Nothing, therefore, was to be gained in speed, and even if the employment of a steam-tug to draw a long train of barges were less costly than the employment of horses, there still remained the difficulty of passing the locks, which would prove so serious a diminution from the saving on level water that the attempt was abandoned.

There is nothing in the account of the experiments on the Bridgewater Canal which shows that either of the difficulties I have alluded to has been overcome, or even so great an advantage gained as that by the screw-steamer. I am, &c.,

BARNETT BLAKE.

Leeds, Oct. 11, 1859.

PATENT LAW.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—The question of the patent law is always unfairly argued; if talent is to be protected as a stimulant to exertion, why is one description of talent, literature, to be protected for twenty-one years at a mere nominal charge, a few copies of the work, which is attended with no greater outlay than the price of a few quires of paper on which the manuscript is written, while the mechanic in many cases must expend large, aye, enormous sums, in making and remaking models and experiments, to be repeated afterwards on a large scale, and even then, however successful he may be, though he attain the most valuable results, if its adoption depend on Government officials or public companies, he may apply to them in vain—insult will be his only recompense, as he will, to a certainty, be treated with silent contempt, even though the sacrifice of human life depends upon their decision. And here is a case in point. Numerous lives have been needlessly sacrificed at railway stations through travellers entering or quitting the carriages while in motion, for which there is not a shadow of excuse, because I could easily and effectually prevent a repetition of those fearful scenes; and yet on three different occasions I immediately wrote to the chairman of the company, stating that it could easily and cheaply be avoided, when they showed such a brutal indifference to the excruciating agonies of their victims that, will it be believed, they did not even deign me a reply! The same with shipwrecks on our coast, the greater number of which I could, to a certainty prevent; but official indifference heartlessly consigns them, their crews and passengers, to destruction. The plan I suggest, and no one could justly complain of such an arrangement, is a per-centage on the article supplied, when he, the patentee, would only pay in proportion to his gains, and at the close of, say the seventh year, he might then be justly required to purchase a renewal of his term, if just it be, or even politic, to tax science while literature is free!

J. C. DE LA FONS.

13 Carlton Hill, St. John's Wood.

CONCUSSION AND PERCUSSION SHELLS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In reference to my communication on the above heading in your number for last week, I beg to add that the different inventors or projectors of percussion and concussion shells were allowed to have a trial of their respective shells on board the *Excellent*, at Portsmouth. Captain Moorsom, R.N., then lieutenant, was the gunnery officer when the experiments were made; the plan of each projector was kept secret from all but the captain commanding and Lieutenant Moorsom. After a time, when the different reports were made to the Admiralty, a shell called the Moorsom percussion shell was adopted, and kept a

profound secret. Its construction is now generally known. There was an error in the date of Colonel Beamish's letter to the editor of the *United Service Magazine*; it should have been of August, 1852, and not 1850.

I am, yours obediently,

J. NORRIS.

Rosherville, 31st October.

THE STELLA LAMP.

THIS lamp, patented in 1857 by Mr. James Broad, of 150 Drury-lane, possesses several features of interest which renders it worthy of the attention of those to whom a cheap light is of consequence. In this category may be, of course, included the whole race of economic housekeepers, and for that class it may be of service to add that it is of great brilliancy, and that the "Stella" oil prepared for it is safe, clean, and healthy. This Stella oil, indeed, appears to us to be of greater importance than the lamp itself, although there are curious mechanical features in the lamp—and also in the method of applying the wick, which is new, and extremely simple. Stella oil will not light like camphine or naphtha, and other dangerous substances now used for burning, and hence one great element of its harmless nature, to which is added the fact of the absence of odour when not inflamed (for then there is none) being of a healthful character. Nor does it evaporate, freeze, corrode, or thicken, but on the contrary, as far as experience goes, it keeps its liquid character intact throughout all temperatures. It, moreover, lights very quickly, and the result of experiment shows a saving of one half over colza oil. We may have more to say of it after longer acquaintance.

THE INTENDED NEW COPPER OR BRONZE COINAGE.

It is known that the Government intend to issue a new coinage of a bronze alloy, to replace the existing copper coinage; and we may now state that the arrangements have been advanced so far that in Manchester there have been constructed the engines to drive the stamping presses to be used, and also the boilers needed for that purpose. The engines and boilers have been made by Messrs. R. Ormerod and Son, of the St. George's Iron-works, Chester-road, Hulme. The latter have already been forwarded to their destination, and the former will follow next week. That destination is the works of Messrs. H. Heaton and Sons, of Birmingham, who have, we are told, executed all the copper coins struck for this country for many years, and who also successfully competed for the execution of the new French currency issued by Napoleon III. The pair of engines are upon an improved direct action principle, and of 50 horses' power: some patented arrangements of Mr. W. B. Johnson (who is connected with Messrs. Ormerod's establishment) being introduced. The frames are vertical instead of horizontal; it being supposed that strength and some other advantages are thus gained. The cylinders are of 20 inches diameter, the stroke being 4 feet. The fly-wheel has a diameter of 18 feet and weighs 13 tons; and the engines being intended to make from 36 to 40 revolutions a minute, the wheel will be speeded to 60 revolutions. The power will be given off from the axle, close to the fly-wheel, so that little or no checking strain should fall upon the engines. But as the metal to be used for the new coinage will be very much harder than copper, and as in striking coins from the latter metal the resistance will sometimes check, and even stop, the machinery, there have been special appliances added to these engines, which, by means of levers, will enable wheels to be slipped and the engines in effect thrown out of gear, while other levers will enable the working arrangement to be gradually and easily restored. The engines are beautifully finished. The two boilers are each 25 feet long and 5 feet 6 inches in diameter; with a 2 feet 9 inch circular flue, fitted for firing at each end, so as to secure more rapid production of steam, and an almost complete burning of smoke. The steam pressure is to be 60lb. It is estimated that two

or three years, at least, will be needed for getting in and replacing the existing copper coinage.—*Manchester Guardian.*

SIR HOWARD DOUGLAS'S SCREW PROPELLER.

We are requested to support the remarks already made by ourselves on this subject by the following "Opinion on Sir Howard Douglas's claim to the Invention of the Improved Screw Propeller," which is identical with the opinion already expressed in our article on page 194 of our number for September 23, 1859:—

"I have very carefully examined into the claim made by General Sir Howard Douglas in regard to his being the first to devise the screw propeller blade of the particular form shown and described at page 61 of his work on 'Naval Warfare with Steam.' This propeller blade consists in a modification of the Admiralty screw propeller, each blade of which was formerly made of about one-sixth of a helix or complete screw, with the forward or leading edge, and also the after edge, perpendicular to the shaft, consequently, such a blade increased in width the further it proceeded from the axis, and was widest at its outermost edge or periphery.

"Sir Howard Douglas, as I understand his claim, alters this propeller blade in respect to its leading or forward edge only; and he does so by removing parts of such forward edge, so that, in place of its being a straight line, he makes it into a convex curved line; and he leaves the after edge of the blade as heretofore.

"If the above be the correct expression of Sir Howard Douglas's claim, I am clearly of opinion that he was the first to devise and publish that particular form of screw propeller; and I am further of opinion that, whatever be the advantages which may arise from the use of that propeller blade, to Sir Howard Douglas will be due the merit of having originated it.

"I am intimately acquainted with Mr. Griffiths' screw propeller blades; and I can only imagine that that gentleman, when he wrote the letter to the *Times* newspaper on the 30th August last, was uninformed of the precise nature of Sir Howard Douglas's claim, or he would not have fallen into the error of supposing that Sir Howard Douglas claimed his (Mr. Griffiths') previous invention. It is of the essence of Mr. Griffiths' invention and of his patent, that screw propeller blades should become 'narrower or tapered towards their outside extremities, in contradistinction to the form hitherto adopted of increasing the width of that part of the blade.' Now, Sir Howard Douglas's propeller blade does go on increasing in width as it proceeds outward from the axis, and it is widest at the periphery; consequently, his blade is the reverse of that invented by Mr. Griffiths.

"I would further state that the giving a convex curved form to the forward or leading edge of a screw propeller was not new either to Sir Howard Douglas or to Mr. Griffiths; Lowe and others having used and published descriptions of screw propeller blades with curved forward or leading edges; but these propellers differed in other respects both from those of Mr. Griffiths and also from those of Sir Howard Douglas.

"(Signed) WILLIAM CARPMAEL,
24 Southampton-buildings.

LIST OF NEW BOOKS.

Beale's Illustrations to "How to Work with Microscope," 1s. 6.
Ency. Met., Rankine, on the Steam-Engine, 12s. 6d.
Euclid's Elements, Books 1-6, by Playfair, 11th edit., by Kelland, 5s.
Presenlin's Qualitative Chemical Analyses, 5th edit., by Bullock, 9s.
Journal of Royal Engineers in Crimea, by Elphinstone, 4 vols., 84s.
King's Study-Book of Mediæval Architecture and Art, Vol. II., 3s.
Marshall's Index Ready Reckoner, for Wages, 2nd edit., 26s.
Page's Handbook of Geological Terms and Geology, 6s.
Parkinson's Treatise on Optics, 10s. 6d.
Pepper's Boys' Play-book of Science, illustrated, 6s.

The splendid show of chrysanthemums in the two Temple Gardens are now open to the public (free) every day from nine till dusk. Visitors are respectfully invited to an inspection of the extraordinary collection of pompones, a dwarf variety of this beautiful autumn flower, in the garden of the Middle Temple; the entrance to this garden is from the broad flight of steps in front of the fountain, within a few minutes' walk of the larger garden, and near Essex street.

NOTICES.

The *MECHANICS' MAGAZINE* will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

OUR APPEAL.

We have to express to several gentlemen the earnest and grateful thanks of the person referred to in the appeal made at page 284 of our last number. To her thanks we would add our own, for the prompt and efficient aid which several of our readers and friends have responded to our statement. Among the sums already received are the following:—J. L., £4; L., £2; R., £2; H. C., £2; T. S., £1 ls.; C., £1; B. N. and Co., 10s. 6d.; P. P., 10s.; W., 10s.; H. A. G., 10s.; S. L. T., 10s.; J. N., 10s.; B., 5s.; T. L., 5s.; T. B. D., 5s.; J. G., 5s.; J. P., 2s. 6d.; Anon (Norwich), 2s. We shall have others to announce next week—we hope many others.

Our Weekly Gossip.

Mr. John Macgregor, of the Temple, Barrister-at-law, has published the following memoranda in the *Journal of the Society of Arts*:—"In the matter of the broken bell at Westminster, perhaps we might possibly learn from the Russians what is to be done in making a better job of the next casting. Every person knows how celebrated Russia is for the size, the tone, and the numbers of its church bells. Some weeks ago I was at Kimra, a small town on the Volga, in the centre of Russia. Part of the church tower had been lately consumed by fire, and the bell had fallen from a height of fifty feet, and embedded its edge about two feet in the stone pavement below. This bell weighs more than sixteen tons, that is, it is two tons heavier than the Westminster bell, yet it survived this fall, and is still sound, without even a crack. Let us bring this bell to London, and let it toll the time until the clockmakers settle their squabbles, and a better Big Ben is cast." We must add, we do not think it necessary to go to Russia for enlightenment on this question, nor need we wait "until the clockmakers settle their squabbles," because "clockmakers" have no squabbles to settle. The one thing to be done is to get the matter out of Mr. E. B. Denison's meddling hands, then all things will probably go rightly.

The same gentleman in the same place says:—"Mr. J. W. Carile calls attention to the large quantity of sawdust and wood-cuttings wasted or burned without effective purpose. This is an important subject, when we consider the enormous heaps of sawdust found near timber-works in Europe and America, the danger from fire if they are left near the mills, the expense of carting them to a distance, the valuable space they occupy, the destruction of fish caused by casting the sawdust into the rivers, and the trouble of burning this material to avoid these disadvantages. I was much struck with this when passing through Sweden last week; and it occurs to me that it may be well to mention that I saw a boiler-furnace burning crude sawdust, entirely unprepared and unmixed, in successful operation last summer, at St. John's, New Brunswick. I do not recollect exactly the construction of this furnace, but I think that Mr. J. Robinson, the proprietor of the extensive saw-mills where it is used, would gladly send a description to any person who may apply for it." Mr. Macgregor deserves thanks for these suggestions.

Captain Norton writes:—"I beg leave to enclose the copy of a letter from the Count Stuart d'Albini, on the subject of my gossamer cartridge, samples of which I had the pleasure of leaving at your office on the 24th instant."

"Dear Sir,—I have the pleasure to acknowledge your obliging letter, and the gratifying samples of your admirable and valuable cartridges. I thank you very much for the opportunity of judging of them by inspection. I perceive at once all their value, and appreciate entirely their admirable ingenuity, efficiency, and simplicity. Their practical operation in the field will be of the highest value, and

ought immediately and generally to supersede the use of any other hitherto introduced. I shall not fail to bear testimony to their pre-eminence, and beg of you to receive the sentiments of high esteem and consideration with which I am, yours very faithfully,

"THE COUNT STUART D'ALBINI.

"11 Duchess-road, Eggeston, Birmingham, Oct. 25,
"Captain Norton."

"N.B.—Many years ago I made what is called the skin cartridge, but found it liable to decompose and rot. All varnishes to prevent damp are worse than useless, as they clog the interior of the barrel.—J.N."

Dr. McCormack, of Belfast, writes:—"The natural and pardonable solicitude of the country on the subject of the national defences, has suggested to me the practicability and desirability of a description of steam floating batteries, of shallow draught, but of great beam, carrying heavy breach-loading ordnance—vastly superior, I conceive, to any in hand, or hitherto proposed. Compartments should be introduced, along with every expedient calculated to ensure strength and safety. The upper or weather deck should be arched somewhat, and otherwise bomb-proof: the sides heavily plated with wrought iron plates; the ends pointed; the rudder and steering apparatus, with the high-pressure locomotive engines, so arranged as to permit the vessel to steer either way with equal facility, the paddles or screws working within a groove in the vessel's bottom. Watson's ventilators would insure a supply of air; bull's-eyes set in the deck, and plate-glass sliding panes covering the ports or embrasures, when the vessel was not in action, would yield light; otherwise, the ports should be covered with folding iron shutters, equally strong with the vessel's sides, to be closed at night, or in heavy weather and during action, only opening in full when the guns were run out for discharge. At night, the electric light would shed a brilliant light on the surrounding darkness, while, at the same time, it might be obscured on the side of danger, or even extinguished at pleasure. These batteries would act à *feu d'eau*, or at the water level, the most efficient position of any; they would be on the watch day and night, and at all hours. By having a sufficient number, the crews of men and boys would not be unduly harassed by too prolonged duty. As the present coast-guard, as at present arranged, would be no longer needed, the men comprising it would go far to man the boats on duty. As the crews might spend half their time on shore, the men would not be too long separated from their families. They would be efficiently trained to the use of heavy ordnance; and as the rafts or floating batteries, by telegraphic signals, could be concentrated on the point or points of danger, the result, I submit, would be an infinite improvement on the heavy, lumbering, inefficient ships of war on which we now alone too much depend, while a degree of security would be realised for our shores, not neglecting other effective measures, that might well bid defiance to open force or wily snare on the part of any opponent or opponents whatsoever."

The following note is curious:—

12 Newport Street, L Square, 1859.

GENTLEMEN,—Will you be kind enough to accept the following supposition? I believe that I have found out the means to take respiration under water, and that I can remain any time I like; and also that the water will not affect any part of the body of the diver,—similar to the invention which enables a man to walk through a flame of fire without receiving hurt. I intend to put it to the test, which if it answers to my idea, without doubt it will be beneficial to the divers. I spoke to Mr. Heincke of the Polytechnic Institution yesterday on the subject.

Your obedient servant,

LAURO CECCONI.

An old subscriber may fairly have space for the following letter:—

Elm Cottage, Oct. 28, 1859.

GENTLEMEN,—I have just read in August 19, 1859, No. of your Magazine p. 113, middle column, from the bottom 13 lines, that many officers "are inclined to recommend a recurrence to the old paddle wheel." I have taken the *MECHANICS' MAGAZINE* from the very first number. I have for many years frequently set forth what I consider a desirable alteration; that is, placing the paddle wheels amidships under an air-tight case, the float board working between an inner and outer bottom of the ship. Some of the first engineers in the kingdom have pronounced the principle sound if it could be reduced to practice. It occurred to me a few days ago, when on board the Great Eastern, that to fill a large space as the two paddle wheels would occupy, with compressed air of sufficient elastic force to resist

a column of water from the load line to the inner bottom would take a large air pump, and consequently require great engine power; to obviate this it occurred to me that the paddle boards might be fixed to an air-tight drum, such as proposed by Captain Selwyn to pay out the Atlantic cable, and that this would so limit the space in the paddle case, that a comparatively small air-pump would be required. If the plan is feasible, the motive power would be free from all danger from fouling, or shot, and the point of propulsion would be near the centre of gravity, and do away with much of the unpleasant vibratory motion felt in paddle ships. Yours most obediently,

C. P. BANKS.

Tickets of admission to the public to view the Franklin relics at the United Service Institution will be issued this week for Monday, Tuesday, and Saturday in next week and the weeks following, in limited numbers, as the accommodation that can be furnished by the institution is inadequate to meet a large number of visitors. The tickets are to be obtained from Stanford, Charing-cross; Graves, Pall-mall; Mitchell, Charing-cross; Parker, West Strand; Potter, Poultry; and Byfield, Charing-cross.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 800, 805, 821.
BOILERS AND THEIR FURNACES, &c., 806, 812.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., None.
SHIPS AND BOATS, including their fittings, 798, 807, 822.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 797, 804.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 803, 811, 814.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 802.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 810.
LIGHTING, HEATING, AND VENTILATING, 823.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., None.
METALS, including apparatus for their manufacture, 826.
CHEMISTRY AND PHOTOGRAPHY, 799, 819.
ELECTRICAL APPARATUS, None.
WARFARE, 798.
LETTER PRESS PRINTING &c. None.
MISCELLANEOUS, 801, 807, 808, 809, 813, 815, 816, 817, 818, 820, 824, 825.

797. J. CARTWRIGHT. "An improved implement for crushing clods and pulverising the surface soil, also convertible into a press wheel roller." Dated March 30, 1859.

The patentee claims the use of the rings or sections with serrated or saw-formed teeth, and the concentric rings, whether used separately or in combination with each other, as well as the method of converting the implement into a press wheel roller by reversing the frame and shafts. *Patent completed.*

798. C. P. COLES. "An apparatus for defending guns and gunners in ships of war, gun-boats, and land batteries." Dated March 30, 1859.

This consists of a large convex shield covered with thick metal, and mounted upon a platform which is capable of revolving and which carries the gun or guns. Apertures are formed in the shield to allow the muzzles of the guns to pass through. *Patent completed.*

799. W. GOSAGE. "Improvements in the manufacture of certain alkaline silicates, and in the production therefrom of liquor silicis or liquid flint." Dated March 30, 1859.

This consists, 1, in using carbonate of potash, which has been previously deprived of sulphate of potash or sulphate of soda, and thereby obtaining soluble glass of such quality that the solution or "liquid flint" produced from it is free or nearly free from alkaline sulphuret. 2. In purifying liquid flint made from soluble glass, so as to destroy such alkaline sulphuret as may be present therein. The inventor effects such purification by means of oxidising agents. *Patent abandoned.*

800. A. V. NEWTON. "An improved governor for marine and other steam-engines." (A communication.) Dated March 30, 1859.

This consists in the use of a small steam-engine working independently of the engine whose speed is to be governed, the same being so applied as to drive certain mechanism which effects an unvarying resistance to its motion, and is combined with mechanism driven by the engine to be governed, the whole being so arranged as to work a regulating valve which controls the supply of steam to the last-named engine. *Patent completed.*

801. W. SMITH and E. SMITH. "Improvements in means or apparatus for the purpose of regulating the flow or passage of fluids." Dated March 30, 1859.

This relates to cocks in which the closing of the passage is aided by the pressure of the fluid acting upon a valve. The valve is formed at its inner surface somewhat egg-shaped, and it is recessed on the opposite surface to receive and form a sort of rim round the india-rubber packing, which is thereby prevented from spreading. The stem of the valve passes through a hole formed for it in the case of the cock or tap, where it may have a head to open it, or be connected to a lever formed and weighted to aid the closing of the valve. There are modifications included. *Patent completed.*

802. J. LACY, S. SIMPSON, and H. SMITH. "Certain improvements in machinery for preparing and spinning cotton and other fibrous materials." Dated March 31, 1859.

This particularly applies to roving frames and to mules and throstles, and consists in unwinding the bobbins by rollers, or other friction surfaces, to avoid the strain on the fibrous material, and to effect a uniform delivery of the slubbings or rovings. *Patent completed.*

803. C. PICKERING. "Improved apparatus for brewing." Dated March 31, 1859.

This relates to a portable apparatus for brewing. It is proposed, 1, to make the copper case fluted or corrugated, to hold fire clay or cement. 2. To make the mashing tun square; also to form a chamber round the mashing tun into which hot liquor is to be admitted for maintaining the heat of the wort. Also to adopt a novel arrangement of gear to the mashing tun. 3. To make the cooler in two parts. 4. To make the circulating channels or conduits of corrugated metal. 5. To fit the workings squares or "gyle-tuns" in the mechanical agitators; also the balm separator to separate the yeast from the beer. *Patent abandoned.*

804. R. C. ROSS. "Improved apparatus for cultivating soil." Dated March 31, 1859.

Under one modification, the digging or cultivating details are carried upon a simple rectangular frame or carriage mounted upon wheels, and arranged so as to be drawn by horses or ropes. The digging mechanism is of the rotatory kind, a series of digging blades or forks being mounted upon a revolving drum or frame, which is driven by a strap or otherwise from one of the axles of the supporting wheels. *Patent abandoned.*

805. T. IVORY. "Improvements in rotary engines." Dated March 31, 1859.

This consists, 1, in causing the impelling fluid while admitted at the circumference, to act directly on an area near the centre of the circle of revolution, and in so arranging the parts of an impulse rotary engine as to produce this effect. 2. In an arrangement for working expansively the steam, or other elastic fluid. 3. In adapting and applying to rotary engines in which a solid piston is made to travel within a steam channel, the arrangements appertaining to the first and second heads of the invention. 4. In adapting and applying the same arrangements to the recoil engines described in a previous patent, dated 30th July, 1857. 5. In obtaining an increased effect from the motive fluid in engines on the "Barker's mill" principle by the arrangements above alluded to. 6. In obtaining the expansive rise of elastic fluids in impulse rotary engines, by means of a hollow arm or chamber opening into a steam channel at the circumference. *Patent completed.*

806. T. IVORY. "Improvements in steam-boilers, and furnaces for the same." Dated March 31, 1859.

This invention comprises various features. We cannot quote the specification at sufficient length for an intelligible abstract. *Patent completed.*

807. A. MORTON. "Improvements in sextants or quadrants for nautical purposes, and which are also adapted to the measuring of altitudes or angular distances." Dated March 31, 1859.

The object here is simplicity of construction, and adaptation of parts of instruments for measuring altitudes or angular distances. The measuring of angular distances between any two objects may be obtained by the use of a single reflector. The rays are only once reflected, though several reflectors may at the same time be employed. *Patent completed.*

808. D. B. WHITE. "An improved indicating gauge-lead, or plummet." Dated March 31, 1859.

This consists in a particular construction of, and adaptation to, a cord or line for sounding, whereby the depth of the bed or bottom may be ascertained by the formation of an electric signal when the plummet reaches the bottom. *Patent abandoned.*

809. J. S. BATHSON. "Improvements in generating steam, and in apparatus employed therein." Dated March 31, 1859.

This relates to a former patent, dated 30th December, 1858. The invention comprises various modifications, and is not fully described apart from the drawings. *Patent completed.*

810. F. MORTON. "Improvements in the construction of fences, and the posts or pillars for the same, parts of which improvements are also applicable to the construction of gate posts or poles for telegraph purposes, or for signal posts." Dated March 31, 1859.

This relates more particularly to the construction of strained fences, and the object of this part of the invention is to draw the strands, cords, wires, &c., up to tension, and to keep them tightly strained, and also to allow of their being slackened with facility. This the patentee effects by passing the strands, cords, wires, &c., through rollers, barrels, or pulleys, provided with any contrivance whereby rotary motion may be communicated to them. *Patent completed.*

811. W. E. NEWTON. "Improvements in mills for cleaning rice." (A communication.) Dated March 31, 1859.

This relates to a mill composed principally of a pestle and mortar, and consists in attaching the pestle to a rod which passes through the bottom of the mortar containing the rice. To this rod a reciprocating motion is imparted in a vertical direction, power being applied from a crank to the rod, which extends through the bottom and projects below the mortar. *Patent completed.*

812. A. V. NEWTON. "Improvements in the construction of steam boiler and other furnaces." (A communication.) Dated March 31, 1859.

This consists, 1, in constructing the curve next the fire chamber forming one part of the reverberatory combustion chambers, by continuing it upward and towards the opposite curve which extends towards it in a curve of increased radius, so as to cause the two curves, enclosing in part the combustion chamber, to terminate in their overhanging projections in such relation to each other as to ensure a more perfect rotation or eddying of the gases and other products from the fire-chamber in the combustion chamber, and thus enable them to mix intimately with the air admitted to the combustion chamber. The gases thus mixed will be so presented to the incoming current of flame as to ensure their complete combustion. 2. In forming the curves of metal protected from the extreme heat of the fire-chamber by an additional segmental or curved plate which shall form a heating chamber (having a horizontal orifice above) for heating the air before passing into the combustion chamber. *Patent completed.*

813. D. K. CLARK. "Feed-water heating apparatus." Dated April 1, 1859.

The patentee claims a method of heating the feed-water of steam boilers by the introduction of the water in one or more currents or jets, into one or more confined channels, and the injection of one or more jets of steam from the exhaust or otherwise into the same passages in immediate contact with the water, so as forcibly to impinge upon, and to draw, suck, or project the water through the passages, and to immediately disperse and intermix with it on the way, thereby effecting the immediate condensation of the whole or part of the steam, and consequently the heating of the water within the passages. *Patent completed.*

814. F. P. A. AUBERTIN. "An improved preparation of food for herbivorous animals." Dated April 1, 1859.

This consists, 1, in the application of mucilage of the cactus opuntius in combination with chopped hay, straw, lucern, bruised oats, barley, or other grain or seeds usually employed in the preparation of food for horses. *Patent completed.*

815. I. SIGISMUND. "Certain improvements in the manufacture of artificial teeth, and in the apparatus connected therewith." (Partly a communication.) Dated April 1, 1859.

The inventor uses the tusk of the morse or walrus in the manufacture of artificial teeth. *Patent abandoned.*

816. R. A. BROOMAN. "Improvements in machinery for solidifying, pressing, and moulding." (A communication.) Dated April 1, 1859.

This relates to a previous patent, dated April 14, 1857, and consists in driving plungers forward directly

by means of an eccentric, which subsequently draws them back again. The plunger rods are formed with protails, orjections, which enter and are guided by grooves in a plate round the central shaft. This plate is cut away at intervals to allow of the parts most subjected to friction being lubricated. *Patent abandoned.*

817. R. A. BROOMAN. "A new preparation of indigo for dyeing." (A communication.) Dated April 1, 1859.

This new preparation is obtained by treating indigo with alkaline earths partly saturated with such acids as sulphurous, phosphorus, cyanhydrous. *Patent abandoned.*

818. W. E. NEWTON. "Improvements in cricket bats." (A communication.) Dated April 1, 1859.

This consists in constructing the blade of the bat with a mere shell of wood, and a filling of cork or other elastic material, and in constructing the handle of a hollow tube of wood, with a strip of whalebone, or other flexible or elastic material running through the centre and down into the blade. *Patent completed.*

819. W. E. NEWTON. "An improved process of manufacturing sulphate of lead, carbonate of lead, nitrate of potash, and sulphate of soda." (A communication.) Dated April 1, 1859.

This consists, 1, in dissolving the lead in acetic or nitric acids, and in decomposing the soluble nitrate, or acetate thus formed by means of sulphuric acid, by which an insoluble precipitate of sulphate of lead is formed, the nitric or acetic acids being set free to be used in dissolving another portion of the lead. 2. In decomposing the sulphate of lead, as above obtained, by means of carbonate of potash, and nitrate of soda, whereby are obtained carbonate of lead, nitrate of potash, and sulphate of soda. *Patent completed.*

820. J. J. DAVIS. "An improved pad, applicable for inking, damping, and other like purposes by hand." Dated April 1, 1859.

This relates to the application of a pad mounted on an axis so that it can be turned to present different surfaces, as may be required for the inking or colouring of stamping surfaces, and for damping or gumming stamps, envelopes, &c., by hand. *Patent abandoned.*

821. W. TOD. "Improvements in marine steam engines." Dated April 1, 1859.

This comprises a variety of detail to which we cannot here give space. *Patent completed.*

822. Y. THOMAS. "An improved propeller for ships, vessels, boats, and water wheels." Dated April 1, 1859.

This invention is not described apart from the drawings. *Patent completed.*

823. J. DESMET-SEAUT. "An improved gas-burning and lighting apparatus." Dated April 2, 1859.

This consists in a peculiar arrangement of apparatus having rotatory burners, suitable for ordinary and ornamental gas-lighting purposes. The apparatus consists of a closed cup or vessel of glass, or other suitable material, within which a recipient is fixed containing water for purifying the gas on its passage through openings in a supply pipe, to a rotating pipe, which is partly immersed in water; this latter pipe turns on a pivot and is caused to rotate by the pressure of the gas on its passage through it, and communicates such rotatory motion to the branches or burners in communication with it, and which may be in a spiral or other form. *Patent abandoned.*

824. A. RIFLY and J. ROBERTS. "Improvements in machinery for striking or scraping leather and tanned or untanned hides." Dated April 2, 1859.

The main object of this invention is the production of a machine which will approach as near as possible the action of the hand—that is, to give to the knives which act upon the hide a direct backward and forward horizontal motion over the surface of it, and at the same time a motion of rotation on their edges in a plane nearly at right angles to the former, and by means of these compounded motions to excel the effects produced by the knife when guided by the hand. The patentees produce three distinct motions within the knife or knives, two of these motions may be said to result from effects transferred to the knives, the third, from the action within them, the resultant of the whole three being the twisting or oscillating motion before alluded to. *Patent completed.*

825. J. HALL and J. S. SPARKES. "An improved application of machinery for the purpose of hoisting, lowering, pulling, or drawing weights." Dated April 2, 1859.

This consists in the application of what is called in mechanics the endless screw in combination with the wheel and axle to crabs, cranes, windlasses, and that class of machines. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Aug. 29, 1859.

1968. R. Beasley. Improvements in machinery for printing and for numbering and perforating documents. (A communication.)

Dated Sept. 13, 1859.

2084. W. B. Adams. Improvements in the permanent way of railways.

Dated Sept. 21, 1859.

2146. G. K. Geyelin. Improvements in machinery for making solid, hollow, and perforated bricks, also tiles, drain and socket pipes.

2150. G. D. Robinson. Improvements in apparatus for regulating the pressure of gas and other fluids.

Dated Sept. 28, 1859.

2176. R. Kay. Improvements in preparing and bleaching textile fabrics and materials, and in the machinery or apparatus employed therein.

Dated Sept. 28, 1859.

2196. J. F. Stanford. An improved apparatus for giving warmth to the lower extremities and members of invalids and others when travelling, or in churches, chapels, theatres, rooms, carriages, and other similar places, and on ship-board, and also for airing carriages.

Dated Sept. 29, 1859.

2204. T. Allan. Improvements in applying electricity for telegraphic purposes, and in apparatus employed therein.

Dated Sept. 30, 1859.

2214. E. Sonneborn. An improvement in the manufacture of cement.

Dated Oct. 1, 1859.

2230. J. Baughan. Improvements in the manufacture of soap.

Dated Oct. 3, 1859.

2236. R. A. Brooman. Improvements in treating clay, and in the manufacture of bricks, tiles, and other like articles, and in machinery employed therein. (A communication.)

Dated Oct. 5, 1859.

2252. F. J. Dove. Iron clasped bonding plates for joints and other building purposes.

2256. W. G. S. Mockford. Improvements in the manufacture of starch.

2260. T. H. Dodd. Improvements in portable apparatuses for the use of smiths, carpenters, and other workmen.

2262. W. E. Newton. Improvements in blankets used for printing calicoes and other fabrics, and in the mode of washing or cleaning the same. (A communication.)

2264. J. Prichard. Improvements in spurs.

2266. J. Webster. An improved construction of spring for carriages and other purposes.

2268. J. Turpie. Improvements in the fore and aft gaff and boom sails of ships.

2270. G. Long and J. Archer. Improvements in the manufacture of manure.

Dated Oct. 6, 1859.

2272. J. P. and E. Scott. An improved instrument for boring and drilling. (A communication.)

2276. E. O. Tindall. Improvements in machinery or apparatus for crushing or reducing grain, seeds, and other substances.

2278. A. M. Ferry. Improvements in the manufacture or production of oil, and in lamps for burning the same.

2280. A. Hind and J. Lowenthal. Improvements in the manufacture of pottery and china wares. (A communication.)

2282. R. Warry. Improvements in breech-loading ordnance, and in projectiles for the same.

2284. G. and J. Gibson. Improved machinery for raising and removing soil or earth from sewers and other excavations.

Dated Oct. 7, 1859.

2286. W. Brookes. Improvements in securing the tyres of railway carriage and engine wheels. (A communication.)

Dated Oct. 8, 1859.

2290. W. Dawson and T. Singleton. Improvements in apparatus applicable to looms for weaving.

2292. J. H. Johnson. Improvements in the treatment of fatty matter. (A communication.)

2294. P. Robertson. Improvements in preparing, boiling, and fermenting worts, and in maturing beer, spirits, and cyder.

2296. H. Monument and G. Berry. Improvements in apparatus for raising and moving earth, and other matters and bodies.

Dated Oct. 10, 1859.

2297. J. S. Parfitt. A registering nautical velocimeter, for measuring the speed of ships, and also of currents of water.

2299. C. A. Shaw. Improvements in machinery for shaping or bending tinned sheet iron, and other sheet metal. (A communication.)

2300. T. and J. Knowles and A. Rigg. Improvements in machinery or apparatus for shaping, cutting, punching, and drilling metals, which improvements are also applicable to presses.

2301. G. White. Improvements in frames for spinning and twisting yarn of any description of textile materials. (A communication.)

2303. S. B. Parker. A method of, and apparatus for, revivifying oxide of iron and other agents for purifying gas containing metallic particles.

2304. W. Martin, jun. An improved method of damping linen and other textile fabrics.

Dated Oct. 11, 1859.

2306. L. J. Jeannin. A new system of pumps.

2308. C. F. Beyer. Improvements in machinery for boring and drilling.

2307. J. L. Tenting. Improvements in the construction of buffers for railway and other carriages, also applicable to other purposes where springs are employed.

2308. J. L. Tenting. Improvements in the construction of the axles of railway and other carriages.

2309. J. Earl. Improvements in arranging and applying harness to the draft of carriages.

2310. W. D. Hart. Improvements in pressure regulating apparatus for gas burners.

2311. J. Smith. Improvements in breech-loading fire-arms and ordnance.

2312. P. G. Cunningham. Improvements in the construction of artificial teeth and gums.

2313. A. Whytock. Improvements in coating sheets of metal with other metals and other substances.

2314. A. V. Newton. An improved mode of clarifying and defecating saccharine solutions and juices. (A communication.)

2315. F. A. Lohage. An improved construction of water-wheel. (A communication.)

Dated Oct. 12, 1859.

2316. J. Skertchly. Improvements in the manufacture of mosaic and other ornamental tiles and slabs, and in apparatus connected therewith.

2317. G. Scott. Improvements in generating elastic fluids and in the apparatus for that purpose.

2318. W. Day. A direct-action rotary steam-engine.

2319. A. A. D. Hely. Certain improvements in the manufacture of tobacco for smoking purposes.

2320. J. Carrick. Improvements in commodes, water-closets, and other sanitary appliances.

2321. Z. Nuttall. Improvements in looms for weaving.

2322. J. Thomson. An improved form of hydraulic valve and apparatus to be used in the manufacture of gas.

2323. T. Rothwell. Improvements applicable to warehouses and other buildings in which "well-holes" are constructed for the purposes of light and ventilation.

2324. E. H. Baron, J. Wheeler, and L. Tatley. Certain improvements in carding engines for carding cotton, wool, and other fibrous materials.

2325. J. Tangye. A new or improved method of actuating certain kinds of motive power engines, and in the distribution of motive power.

2326. E. H. Taylor. Improvements in apparatus applicable to the permanent-way of railways.

2327. C. H. Southall. An improved apparatus for making and finishing boots and shoes.

2328. C. P. Moody. A method of, and apparatus for, raising grass and other crops on to stacks, which apparatus is also applicable to raising and transferring weights.

2329. T. B. Daft. Improvements in flexible valves.

2330. H. Bright. Improvements in machinery or apparatus for navigating the air.

2331. T. Twells. Improvements in machinery and apparatus connected therewith for embroidering or ornamenting woven, looped, or laced fabrics.

Dated Oct. 13, 1859.

2333. J. Rhone. An indicating meter tap.

2335. J. Hunter. Improvements in machinery or apparatus for ploughing or cultivating land.

2337. L. H. Rousseau. Improvements in steam engines.

Dated Oct. 14, 1859.

2341. F. Levick. An improvement or improvements in the manufacture of iron.

2345. J. Jack. Certain improvements in steam engines and boilers for marine and land purposes.

2347. T. Robinson. Improvements in annealing or softening wire.

Dated Oct. 15, 1859.

2349. W. E. Newton. An improvement in the mode of applying india-rubber, gutta percha, or other elastic substances to give elasticity between the tires or outer rims and the hubs or naves of railway or other wheels and between other metallic bodies. (A communication.)

2351. F. A. Leigh. Improvements in machinery or apparatus for the manufacture of screws, bolts, and nuts. (A communication.)

2353. R. Bates. Improvements in engines for carding cotton and other fibrous substances. (A communication.)

2355. J. Echard. Improvements in machines and apparatus for ploughing and sowing. (A communication.)

2357. J. H. Brown. Improvements in the preparation of gunpowder for loading ordnance and fire arms.

Dated Oct. 17, 1859.

2361. G. Berry. Improvements in the construction of glass and earthenware vessels for containing fluids, particularly such vessels as are intended to contain fluids which may exert dynamic force on the stoppers of such vessels.

2363. L. Vidie. Improvements in transmitting the motion of steam engines.

2366. G. W. Reynolds and E. Dance. A new or improved manufacture of baskets and other articles usually made of wicker work, and new or improved machinery to be employed in the said manufacture.

2367. W. E. Newton. Improvements in preserving and disinfecting organic substances. (A communication.)

2369. J. Bernard. Improvements in the manufacture or production of boots and shoes, and other coverings for the feet, and in the machinery, apparatus, and means connected with such manufacture.

2371. D. Jones. Improvements in self-acting breaks to be used on railways.

2373. W. Hall and A. Wells. Improvements in the manufacture of ropes and cords.

Dated Oct. 18, 1859.

2375. G. Canouil. Cartridges' paper, chemically prepared for percussion fire-arms.

2377. J. Reynolds. Improvements in the manufacture of wrought nails. (A communication.)

2379. G. T. Bousfield. Improvements in machinery for steering vessels. (A communication.)

2381. C. Hill. An improved fastening for stays and other purposes.

2383. W. E. Newton. An improved method of making combs or gills employed in the preparation of fibrous substances. (A communication.)

2385. A. Scheurer-Rott. The preparation of certain substances for fixing colours in dyeing and printing, and for other purposes.

Dated Oct. 19, 1859.

2387. G. Worssam. An improvement in non-condensing steam-engines.

2389. J. Gordon. Improvements in machinery or apparatus for pulping coffee.

2391. T. Spencer. Improvements in the manufacture of carbonate of soda.

2393. C. Cowper. Improvements in photographing on uneven surfaces, and in apparatus for that purpose. (A communication.)

2395. J. J. Bowen. Improvements in manufacturing the pots for containing liquids used by publicans and others.

2397. W. Warne, J. A. Jaques, and J. A. Fanshawe. Improvements in the manufacture of elastic hoops or bands and other analogous elastic articles, applicable to various parts of ladies' and gentlemen's wearing apparel, and in the machinery employed in such manufacture.

2399. J. R. Palmer. Improvements in the manufacture of printing ink and paints and varnishes, and also in the manufacture of lacquers, japans, and blacking.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

2413. J. Avery. Improvements in railroad weightlocks and other platform scales. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Nov. 1, 1859.)

1463. C. F. Vassero. Stereoscopes. (A communication.)

1487. A. P. How. Distilling apparatus.

1492. J. Meikle. Coating ships with asphalt.

1499. A. Barclay. Steam hammers.

1504. W. Russell. Wheels.

1514. H. Doulton. Jars and bottles.

1517. J. Mills. Keys and gibs.

1524. T. Howard. Condensing steam.

1526. C. W. Williams. Steam boilers.

1531. W. Coppin. Raising weights and bodies.

1534. D. J. Fleetwood. Shaping metals.

1535. B. Burton. Fire-arms.

1550. G. Chapman. Knitting machines.

1554. A. Gueyton. Enamelling.

1557. R. A. Brooman. Lithographic presses. (A communication.)

1562. J. A. Wilkinson. Printing presses.

1564. J. Bernard. Boots and shoes.

1574. R. Boyds and A. Harcourt. Composition for protecting structures of iron.

1583. C. H. G. Williams. Dyeing.

1586. J. Simon. Composition to replace lead, &c.

1701. H. Parent. Looms.

1712. G. Welch. Frames for mirrors, &c.

1733. J. King. Distillation of spirits.

1895. R. A. Brooman. Locks and keys. (A communication.)

2038. E. R. Dann and E. Goldschmidt. Bonnet fronts.

2112. J. Beck. Stereoscopes.

2168. J. Gedge. Stamp holder and cutter. (A communication.)

2199. M. L. J. Lavater. Injection bottles.

2214. E. Sonneborn. Cement.

2276. E. O. Tindall. Crushing grain, &c.

2278. A. M. Ferry. Oil and lamps.

2300. J. Earl. Harness.

2331. T. Twells. Embroidering.

2363. L. Vidie. Steam engines.

2371. D. Jones. Railway breaks.

2377. J. Reynolds. Wrought nails. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Oct. 27, 1859.

LIST OF SPECIFICATIONS, &c.,

Published during the week ending Oct. 22, 1859.

No.	Pr.	No.	Pr.	No.	Pr.	No.	Pr.	No.	Pr.
7090	11	7390	10	7500	10	7611	9	7721	10
7260	9	7400	10	7530	10	7630	5	7740	3
7270	10	7410	3	7542	3	7670	7	7750	3
7281	7	7470	9	7550	3	7681	9	7760	3
7330	6	7480	7	7590	3	7710	9	7770	3

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennett Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

ENGINE, *Kingston-upon-Hull*.—Construction and erection of an expansive condensing pumping engine, 85-in. cylinder, at their waterworks at Stoneferry, near Hull. A specification and drawing of Mr. R. A. Marillier, 73 Sowgate, Hull, to November 15th. Tenders to November 23rd, marked "Tender for Engine," Mr. Wells, town-clerk, Hull.

RAILWAY BUILDINGS, *Great Northern Railway*.—At King's Cross Station, extension of provender store, trellis bridge, and conversion of straw store into stables. Plans of Mr. W. M. Brydone, the company's engineer, at King's Cross; and the specification and form of tender on payment of 5s. Tenders sealed and marked "Tender for extension of provender store," must be lodged at Secretary's office, King's Cross station, on Tuesday, November 8th, when parties tendering must be in attendance.

RYDE PIER, *Isle of Wight*.—For the enlargement and improvement of the pier. Drawings, specifications, particulars, and forms of tender, Mr. W. C. Batcliffe, solicitor to the directors of the pier company, to whom tenders, November 15.

WAGGON-WAY, *Newcastle-upon-Tyne*.—For the excavation and other works required in the construction of a line of waggon-way for the Ayre's Quay Bottle Company. Plans, &c., 22 Bridge-street. Tenders, November 7th.

CHURCH, *Ripley, Derby*.—New tower, chancel, and vestry, extension of nave, &c., to the parish church of Ripley. Plans, Mr. R. Barber, architect, Eastwood, Nottingham, after November 28th. Tenders, December 17th.

CEMETERY, *Barnsley*.—For forming and stoning the roads and walks, and also laying out and performing the labour in planting, &c., at the cemetery at Barnsley. Drawings and specifications to Mr. W. H. Peacock, Clerk to the Burial Board, Church-street, Barnsley. Tenders to November 14th.

RESIDENCE, *Patersham, Surrey*.—For J. P. Mumrough, Esq. Specifications, &c., Mr. J. H. Fowler, architect, 32 Fleet-street, London.

HOUSES, *Shipley, Leeds*.—For the several works to be done in the erection of three houses to be built at Victoria Park, Shipley, Drawings, &c., at the office of Mr. A. Jackson, Kirkgate, Bradford. Tenders to November 7.

SURVEY, *Wortley, Leeds*.—For a new survey, plan, and valuation of the township. The plan to be on a scale of three chains to the inch. The township contains 1,036 acres, including about 2,000 dwelling houses. The overseers do not pledge themselves to take the lowest, or any tender. Tenders and testimonials for the above, or for a valuation without survey, may be sent to Mr. J. Stones, assistant overseer. Tenders to November 16.

SUPERINTENDENT OF PERMANENT WAY.—For the Punjab Railway. Will be required to undergo a medical examination, and to proceed to India immediately. Salary £300 per annum. Apply by letter only, stating age, and enclosing copies of testimonials to T. A. Yarrow, Esq., consulting engineer, Gresham House, Old Broad-street, London, E.C.

MINING SECRETARY.—With influence, for a proposed company. Apply to M'Ewen and Glover, C. E., York Chambers, King-street, Manchester.

MECHANICAL DRAUGHTSMAN.—As an assistant to an engineer engaged on works in the country. Must have a good knowledge of accounts, and be able to prepare scale and working drawings from sketches. One who has been brought up in the workshop preferred. Apply with all particulars, to T. W. W. Glynneth, Glamorganshire.

MILLWRIGHT.—For a forge and mill. He must be a thorough good workman, and one who may be fully relied upon to keep the works in repair. No one need apply who cannot produce good testimonials. Application to Mr. Parke, bookseller, High-street, Wolverhampton.

A MILLWRIGHT, AN ENGINE-FITTER, AND AN AGRICULTURAL IMPLEMENT-FITTER.—Apply to Mr. Mellard, Kent Foundry, Rugeley, Staffordshire.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 11, 1859.

THE NEW SCREW LINE-OF-BATTLE
SHIP VICTORIA.

THIS magnificent ship which will be launched on Saturday from Portsmouth Yard, in the presence of Her Majesty and the Royal family, deserves particular notice as being larger than any line-of-battle ship now afloat, and also as being the first three-decker that has been designed expressly as a screw-steamer. Her actual displacement when at her load-line will amount to very nearly 7,000 tons, which is greater than that of every other ship of war by nearly 1,000 tons!

We have at present afloat five screw three-deckers—the Marlborough, Royal Sovereign, Duke of Wellington, Royal Albert, and Royal George. These were originally designed for sailing ships; the first three by the late Surveyor of the Navy, Sir William Symonds; the Royal Albert by the late Mr. Oliver Lang. The Royal George was built on the lines of the old Caledonia, and was launched at Chatham in 1827. To adapt these vessels for the reception of the screw, they were altered as follows:—the Marlborough was lengthened in midships and at each end, and was also increased slightly in breadth; the Duke of Wellington and Royal Sovereign were lengthened in midships and by the stern; the Royal Albert was lengthened by the stern; and the Royal George only had the screw aperture cut in her deadwood, and was not lengthened at all.

The following table, showing the comparative principal dimensions of these ships and of the Victoria, will be found interesting to those of our readers who regard with satisfaction and pride any addition to the naval resources of the country:—

NAME.	Guns.	Horse Power.	Length between Perpendiculars.	Extreme Breadth.	Depth in Hold.	Burthen in Tons.
Royal George	102	400	205 ft. 7 in.	54 ft. 6 in.	23 ft. 3 in.	2616
Royal Albert	121	500	232 ft. 9 in.	61 ft. 0 in.	24 ft. 8 in.	3725
Duke of Wellington	131	700	240 ft. 6 in.	66 ft. 1 in.	24 ft. 8 in.	3771
Royal Sovereign	121	800	240 ft. 6 in.	66 ft. 0 in.	24 ft. 8 in.	3739
Marlborough	131	800	245 ft. 6 in.	61 ft. 2 in.	25 ft. 10 in.	4000
Victoria	121	1000	250 ft. 0 in.	60 ft. 0 in.	26 ft. 10 in.	4112

It will be observed that the Victoria, though larger than the Marlborough, does not carry so many guns. The armament of the Victoria is, however, the heavier of the two, as she carries on the middle and lower decks nothing but 64-pounders, as will be seen by the following table:—

	Ins.	Cwt.	Feet.	No.
Lower Deck ..	8	65	9 0	51
Middle Deck ..	8	65	9 0	50
Main Deck ..	32 prs.	56	9 6	32
Upper Deck ..	32 prs.	42	8 0	26
Do. do. ..	68 pr. pivot	95	10 0	1
Total				121

The engines of the Victoria are by Messrs. Maudslay, Sons, and Field, and are of the nominal power of 1,000 horses.

The Duncan, 91, Prince of Wales, 131, and Royal Frederick, 91, all screw-ships, and building under roofs contiguous to that of the Victoria, are to be launched by the end of the present financial year.

The Royal Alfred, a 91-gun screw-ship, is to be laid down immediately on the slip vacated by the Victoria.

The Victoria's keel was laid in the early part of February, 1858. She has been, therefore, but three years and ten months building. We recently had the satisfaction of inspecting her, and in justice to Mr. Abethell, the Master-Shipwright of Portsmouth Dockyard, under whose superintendence she has been built, we must state that as a specimen of sound and careful shipbuilding the Victoria cannot be surpassed. As Her Majesty the Queen will attend the launch in person, it is generally expected that her appreciation of Mr. Abethell's services in this respect, and of his eminence as one of the foremost naval architects of the country, will be marked by Her Majesty conferring the honour of knighthood upon him on the occasion.

UNSINKABLE SHIPS.

WE have received from Mr. Atherton a lengthy communication respecting our last week's article on the above subject, in which we are requested to insert Mr. Atherton's "letter of the 11th ult." in full as it appeared in the Society of Arts' "Journal." Why the request is made we cannot divine; nor can we comply with it, for we have no space to devote to matter which would convey nothing novel or interesting to our readers. Mr. Atherton in the letter on another page implies, it is true, that we have put a forced construction upon his statements, but as he makes no attempt to prove the implication he can have no claim upon us in the matter. We might also, we think fairly, decline to insert the communication now sent to us, for it throws but little light upon the questions which we submitted to Mr. Atherton's consideration; but, on the whole, we think it better to give it a place in our columns.

It will be seen that Mr. Atherton entirely admits the truthfulness of our suggestions on the necessity of making the light material of which he speaks fireproof. He is, however, less explicit on the other and more important question, viz., what the design of the unsinkable war ship is to be. We are really afraid he has taken no pains whatever to give a practicable form to his propositions even in his own mind. At the first glimpse of the difficulties which we pointed out he abandons, in point of fact, an important part of his proposals, for he now tells us that "the property of being unsinkable does not necessarily imply that such vessels shall have no stowage below the level of the load water line which may be appropriated to machinery." But the truth is, Mr. Atherton's first suggestion (made in January last) was that the ship should be, "up to the line of its load displacement, a solid mass of material," and he has nowhere until now repudiated this part of his plan.

But we need not pursue these considerations at present. Mr. Atherton's fundamental idea may be a good one; indeed we have ourselves a presentiment that unsinkable war ships, at least for purposes of home defence, will one day be devised. But the difficulty of producing them will lie as much in giving form to a light material as in procuring such a material, and we are sorry to find that Mr. Atherton is unable to add anything to our knowledge on either point. Nevertheless, good may arise from the introduction of the subject to public attention, and on this ground Mr. Atherton deserves praise. If the Council of the Society of Arts can adopt any means of hastening the realization of Mr. Atherton's ideas, they too will earn the approbation of the public.

THE MAIN DRAINAGE OF THE METROPOLIS.

METROPOLITAN people are beginning to awake to a very alarming fact, viz., that the great main drainage scheme is a gigantic blunder. Readers of this Magazine will not be startled at this circumstance, because we have all along exposed the folly of pouring into our river a vast quantity of material which in water is mere pollution, but which on the land would be inexpressibly valuable. Just now there seems to be a strong disposition on the part of the public to see eye to eye with us in this matter.

In the *Nautical Magazine* for the present month—a journal in which we should scarcely have expected to find a discussion of this subject—we observe a paper by Captain Heckford, setting forth a plan which he has submitted to the Metropolitan Board of Works, as the fruit of twenty years' acquaintance with the rivers of India. Captain Heckford proposes to obtain about twenty-four tons of salt water per minute by means of steam machinery erected on the sea-coast near Brighton, (or any more convenient site,) and to lead this water up to the Thames by means of pipes laid along a line of railway, these pipes branching off into two heads, one in the vicinity of Chelsea Bridge, the other at Blackfriars Bridge. Thus a constant stream of salt water equal to one 6 miles long, 670 feet broad, and 2 feet deep, would be forced into the Thames every month. "I need not point out," says Captain Heckford "the properties of pure salt water when brought into opposition with that now in the river between Chelsea and Deptford, further than that the salt water thus injected would find its way to the bottom of the river, thereby raising it, and consequently the sewage matter, to a higher level; and as the course of the tide is stronger on the surface than near the bottom, the putrid water now in the river would constantly, though gradually, be carried out to sea, and the offensive substance on the bed of the river would be totally destroyed by its saline action." Captain Heckford also suggests that his system of pipes could be connected with all cesspools, closets, &c., and that by means of separate sewers the whole of the feculent matter of the Metropolis might be carried off to any fixed place, and its properties as a fertilizing agent be preserved. The plan could also be applied, he says, to the cleansing of the docks (which materially help to keep the river in an offensive condition), and to supply the place of fresh water, where the latter could be dispensed with.

We advert to these proposals of Capt. Heckford, not for the purpose of discussing his plans—which have less of novelty attached to them than he probably supposes—but with the view of pointing out the expression of opinion which they have elicited from the editor of the *Nautical Magazine*, Captain Beecher, R.N. Having always, he says, been averse to making the Thames the great receptacle for the sewage of our Metropolis, and regretted that a more appropriate application of it has not been found than in the measures of the Board of Works for their great main drainage scheme, he is not sorry to record Captain Heckford's scheme in his pages, since this, at all events in the long run, would be productive of purity, while that of the Board of Works will be productive of impurity, and that to an alarming extent. The fact of a stream of sewage running into this river during the half of every ebb tide must infallibly occasion, he continues, a state of the water in it between the middle of Sea Reach and Barking that is fearful to contemplate. "We tremble," he says, "for the effects of

"poisonous exhalations to which the crews of those ships will be subject that will have to ride out the ebb in that part of our river, and for the unhappy inhabitants of its banks. To us it seems to be bringing down upon them deliberate destruction. The ships, it is true, can avoid it, by not staying at anchor in such a filthy element; but towns are towns, and homes are not so easily shifted." Captain Beecher goes on to say that we must not be surprised hereafter to find that the port of London will see its shipping diminish in consequence, the owners finding some other port where the health of their crews will not be injured by the pestilential vapours which they would have to encounter on the Thames. Such are the opinions of an experienced naval man on this subject.

On the other hand, the present week has brought us the testimony of an enlightened agriculturist upon the question. Mr. Alderman Mechi, of Tiptree Hall, in a letter to the leading journal, says he considers it a public duty to direct attention to a danger of great magnitude which threatens British agriculture, and through it the nation at large—meaning the gradual but sure exhaustion of the soil of Great Britain by our new sanitary arrangements, "which permit the excrement (really the food) of 15,000,000 people who inhabit our towns and cities to flow wastefully into our rivers." The continuance of this suicidal practice must ultimately result, he says, in great calamities to our nation. Science has shown us that the land, to the depth at which it is ordinarily cultivated, contains but a limited and measureable quantity of the elements of our food; that these elements may be readily exhausted, and that they can only be profitably restored by the application of human and animal ordure such as we now waste. A century of abstraction without replacements has reduced the old and once fertile States of the American Union to comparative barrenness, and although by extensive purchases of guano, bones, and feeding stuffs, we are trying to mitigate the evil, we are warned by that great man Baron Liebig that these attempts are but as a drop compared with what we waste. By a false delicacy and a want of knowledge we have been accustomed to deprecate as indelicate the very mention of our *excreta*, but the stern requirements of a rapidly increasing population imperatively demand of us the only profitable and available means of providing food for the people. Increase of population would, but for our sewer system, bring with it increased means of production. Such has been the case in China, where the commercial value of human excrement has ever been most wisely appreciated and availed of. Of course our Boards of Health very properly consider their only duty is to cleanse our towns and cities. It is for our landlords and agriculturists to associate their will and means to convey to the land those precious streams which now exhaust our soil, contaminate our rivers, and impoverish our agriculturists, and those dependent upon them. It may be said we are producing more food than we used to do; no doubt we are, by enclosing wastes, removing trees and fences, cleaner and deeper cultivation, &c., but by these very means and by the application of stimulating substances we are more rapidly hastening the exhaustion of our country. A very large proportion of our population would be starved but for the enormous importations of foreign food.

This is the testimony of Mr. Mechi, and although it contains nothing more than we have many times said, it is desirable to repeat it here once more. Once more, also, we would

reiterate Baron Liebig's words:—"In the year 1855—1856 above ten million cwt. of guano were imported, of which the greater portion remained in England. In the course of half a century above sixty million cwt. of bones have been imported into that country, yet all this mass of manure is not worth mentioning when considered in relation to the arable surface of Great Britain, and is but as a drop when compared to the sea of human excrements carried by the rivers to the ocean."

It often happens in English life that, in reference to some subjects, our only privileges are to pay and protest. This Metropolitan drainage question is an example of this kind of thing. The fewer our privileges, however, the more mindful we must be of them; hence these observations. Hence also the *Times'* tardy action in the matter. "Everybody must feel," the leading journal now tells us, "that it is folly to waste a substance which is urgently needed, and to pour prodigally into our own rivers what, at a heavy cost, we go to South America to fetch. . . . We are burning the candle at both ends. We are paying heavily to lose what we can very ill spare." May we not yet hope to see our river unpolluted and our soil enriched with the waste of this Metropolis?

THE STUDY OF SCIENCE.

It is well that we who have to deal daily with the rough applications of science to common life may sometimes raise ourselves to that higher sphere from which alone the greater revelations of science are visible. Frequent opportunities of doing this are afforded us. The inaugural addresses delivered at the annual meetings of our scientific societies—the Royal Society, the British Association for the Advancement of Science, and others—usually are made the occasions for comprehensive surveys of the whole physical universe, so far as it is at present known to us; and we, for our part, are always inspired and rejoiced by the contemplations thus occasioned. In the address with which Sir David Brewster opened the winter session of Edinburgh University a few days since, we are furnished with so splendid a representation of the spectacle which the natural world presents to the mind of the man of science that we cannot fail to win the attention of our readers to it.

What are the subjects which the student of the natural sciences has to explore? Sir David eloquently answers,—Creations of boundless extent, displaying unlimited power, matchless wisdom, and overflowing beneficence, will at every step surround him. The infinitely great and the infinitely little will compete for his admiration. And in contemplating the great scheme of creation which these inquiries present to his mind, he will not overlook the almost superhuman power by which it has been developed. Fixed upon the pedestal of his native earth, and with no other instrument but the eye and the hand, the genius of man has penetrated the dark and distant recesses of time and space. The finite has comprehended the infinite. The being of a day has pierced backwards into primeval time, deciphering its subterranean monuments, and inditing its chronicle of countless ages. In the rugged court and shattered pavement of our globe he has detected those gigantic forces by which our seas and continents have changed places—by which our mountain ranges have emerged from the bed of the ocean—by which the gold and the silver, the coal, and the iron, and the lime have been thrown into the hands of man, as the materials of civilisation, and by which mighty cycles of animal and vegetable life have been

enballed and entombed. In his astronomical studies, the earth on which he dwells will stand forth in space a suspended ball, taking its place as the smallest of the planets, and like them pursuing its appointed path—the arbiter of times and seasons. Beyond our planetary system, now extended by the discovery of Neptune to 3,000,000,000 miles from the sun, and throughout the vast expanse of the universe, the telescope will exhibit to him new suns and systems of worlds, infinite in number and variety, sustaining, doubtless, myriads of living beings, and presenting new spheres for the exercise of Divine power and beneficence.

But, it must be remembered, objects like these will not be beheld without deranging the thoughts of untutored minds. When first presented to a mind thirsting for knowledge they are apt to disturb its complacent equilibrium and unsettle its convictions. But, said Sir David to his hearers—Should this be the mental condition of any of you, be not alarmed for its results. This species of scepticism is the infant condition of the uncurbed and generous intellect. There can be no firm convictions where there have been no perplexities and doubts, and that faith which comes in the train of early scepticism will finally rest upon an immovable foundation. Credulity, on the contrary, is the disease of feeble intellect and ill-regulated minds. Believing everything and investigating nothing, the mind accumulates errors till its overgrown faith overmasters its untutored reason. Such a facility of belief may, in some cases, claim the sympathy even of philosophy, but when it spurns the strict demands of inductive truth, and plants imagination at the door of the temple of science, it cannot be too severely reprobated or too sternly shunned. "In the present day, indeed, when religion and philosophy are assuming such novel aspects; when the mysterious in revelation is subjected to the scrutiny of philosophy, and philosophy herself straying into the labyrinths of mysticism, and claiming kindred with the supernatural; when the apostolic simplicity of Christian worship is marred by the glitter and the mummery of exploded superstitions, it is necessary to warn you against speculations morally and intellectually degrading. In the blue heavens above, in the smiling earth beneath, and in the social world around, you will find full scope for the exercise of your noblest faculties, and a field ample enough for the widest range of invention and discovery. Science has never derived any truth, nor art any invention, nor religion any bulwark, nor humanity any boon, from those presumptuous mystics who grovel amidst nature's subverted laws, burrowing in the caverns of the invisible world, and attempting to storm the awful and impregnable sanctuary of the future." This is true wisdom as well as true eloquence, whatever Dr. Cumming may think to the contrary.

A great inventor and discoverer himself, it was not to be supposed that Sir David Brewster would miss from his ken, in an address like this, the triumphs of the mechanical and useful arts. The advances which have recently been made in these arts, he tells us, have already begun to influence our social condition, and must affect still more deeply our systems of education. The knowledge which used to constitute a scholar and fit him for social and intellectual intercourse will not avail him under the present ascendancy of practical science. New and gigantic inventions mark almost every passing year—the colossal tubular bridge, conveying the monster train over an arm of the sea; the submarine cable, carrying the pulse of speech beneath 2,000 miles of ocean; the monster

ship, freighted with thousands of lives; and the huge rifle gun, throwing its fatal charge across miles of earth or of ocean. New arts too, useful and ornamental, have sprung up luxuriantly around us. New powers of nature have been evoked, and man communicates with man across seas and continents, with more certainty and speed than if he had been endowed with the velocity of the racehorse or provided with the pinions of the eagle. Wherever we are, in short, art and science surround us. They have given birth to new and lucrative professions. Whatever we purpose to do they help us. In our houses they greet us with light and heat. When we travel we find them at every stage on land, and at every harbour on our shores. They stand beside our board by day, and beside our couch by night. To our thoughts they give the speed of lightning, and to our timepieces the punctuality of the sun; and, though they cannot provide us with the boasted lever of Archimedes to move the earth, or indicate the spot upon which we must stand could we do it, they have put into our hands tools of matchless power by which we can study the remotest worlds; and they have furnished us with an intellectual plummet by which we can sound the depths of the earth and count the cycles of its endurance. In his hour of presumption and ignorance man has tried to do more than this; but though he was not permitted to reach the heavens with his cloud-capt tower of stone, and has tried in vain to navigate the aerial ocean, it was given him to ascend into Empyrean by chains of thought which no lightning could destroy and no comet strike; and though he has not been allowed to grasp with an arm of flesh the products of other worlds, or tread upon the pavement of gigantic planets, he has been enabled to scan, with more than an eagle's eye, the mighty creations in the bosom of space—to march intellectually over the mosaics of sidereal systems, and to follow the adventurous Phaëton in a chariot which can never be overturned.

This is Sir David Brewster's language, not ours; we are content to repeat it, and commend it to our readers.

THE PATENT OFFICE LIBRARY.

WITH reference to our last week's article on the Great Seal Patent Office Library we are enabled to state that Mr. Edmunds, the Clerk to the Commissioners of Patents, avows himself most anxious to obtain a suitable Library for inventors and patentees, and is likewise desirous that this Library should occupy a central position in preference to any other. It appears that Mr. Gladstone, the Chancellor of the Exchequer, is responsible for the present suspension of the arrangements which were in progress in the earlier part of the year. It is only fair for us to state further that we find the land agency mentioned in the article referred to consists in nothing more than certain friendly offices confined to the transactions of a single estate. We offer these explanations with much satisfaction because we find in them ground for hoping that the Library which is so much needed will ere long be obtained. We need hardly tell our readers that this is our only desire and object in connection with this subject, and that we have no reason whatever for speaking of the gentleman before-mentioned with anything but respect.

The trial of the new (French) field-pieces, to which the grooved principle has been applied, went off to the great satisfaction of all parties. The experiment took place in the exercise ground at Saint Maur. The distance allowed for trial was the enormous one of 2,000 metres—the target, consisting of a pole, surmounted by a little flag, was scarcely visible to the naked eye, and yet, in spite of the high wind, every shot told!—*Morning Star*.

Literature.

Ure's Dictionary of Arts, Manufactures, and Mines. New Edition. Chiefly re-written and greatly enlarged. Edited by ROBERT HUNT, F.R.S., F.S.S., Keeper of Mining Records. Illustrated with nearly two thousand Engravings on wood. Part. I. London: Longman, Green, Longman, and Roberts. 1859.

IT is with the greatest satisfaction that we receive the first part of a new edition of the late Dr. Ure's great work, and our satisfaction is heightened by an examination of its contents. Mr. Robert Hunt is exceedingly well fitted to be its general editor, and he has associated with him a staff of gentlemen thoroughly competent to help him with the details of his great undertaking. No one can know better than ourselves how invaluable Dr. Ure's volumes have been to manufacturers and men of science generally; but it must be acknowledged that of late years the progress of science had carried us beyond it in many respects, and a new edition, bringing its articles up to date, was greatly needed. The part before us proves that the need is being most satisfactorily supplied. The 192 pages of this part carry us only to the article "Artesian Wells," which was reached on the 87th page of the edition of 1853, so that the new matter is more than twice as voluminous as the old. This arises, to a great extent, from the introduction of entirely new articles; but it is mainly the result of the extension of the former articles with modern matter. Among the many new articles the more remarkable are 8 pages on Acidimetry, 2 on the Air-engine, 2½ on Algæ, 4 on Aluminium, 7½ on Chloride of Ammonium, and 2½ on the colouring material named Arnatto, Arnotto, or Annotto. Among the extended articles the principal are, that on Acetic Acid, which is extended from 12 to 19 pages, others on Alcohol and Alcoholometry, enlarged from 15 to 23 pages; on Aldehyde, from 7 lines to a page; on Alkali and Alkalimetry, from 13 to 18 pages; on Alloy, from 4 to 11 pages; on Alum, from 8½ to 18 pages; on Amalgam, from 2 lines to a page; on Ammonia, from 1 to 10 pages; on Anchor, from 4 to 9 pages; on Aviline, from 10 lines to 2 pages; on Anthracite, from 20 lines to 3 pages; on Antimony, from 1 to 3½ pages; and on Arsenic and its compounds, from 4½ to 8 pages. We give these details to show the comprehensive manner in which the new edition is being revised. Nor is any expense being spared in the "getting up" of the new edition. The new woodcuts, which are numerous, are exceedingly well engraved, and both the paper and the type are superior to those of the '53 edition. We find great reason to believe also, from a careful examination of this part, that perfect impartiality will be observed in the new and the re-written articles. The chief editor himself, Mr. Hunt, has not scrupled, we observe, to remove from the article on Actinism passages complimentary to himself, which formerly appeared in it. Dr. Ure gave Mr. Hunt credit for being the first discoverer of the actinic principle. Mr. Hunt "remits" it—to use the French Emperor's term—to M. Berard. Again, in the article on Anchors we find a fair and honest account of the various improvements which have been proposed in anchors from time to time, and are not (for once) surfeited with intemperate praises of the Trotman anchor. Indeed, the writer candidly says:—"Although for convenience Trotman's anchor is, as we have already stated, largely used by the merchant steamers, we cannot but feel that the separation of the fluke from the shaft, although it may be in many cases unobjectionable, is attended with the risk that when, in an emergency, the anchor is required, the means of connection may be at fault." According to the announcement the work is to be completed in fourteen parts, forming three volumes; the intervals at which the parts are to appear are not stated—probably are not known, as they may be dependent upon the opportunities of some of the authors. Each

part will, however, be most valuable in itself, and manufacturers and others will be glad to secure each as it appears.

Journal of a Voyage to Australia and round the World for Magnetical Research. By the Rev. W. SCORESBY, D.D., F.R.S., &c. Edited by ARCHIBALD SMITH, Esq., M.A., F.R.S., &c. London: Longman, Green, Longman, and Roberts. 1859.

THE disturbing influence which the magnetism of iron ships exerts upon their compasses has been illustrated by an amazing display of mathematical symbols, but until the establishment of the Liverpool Compass Committee in 1854 very little indeed was done in the way of experimental inquiry into this important subject. This committee, which has rendered valuable services in this respect, was to a great extent due to the labours of the late Dr. Scoresby, and for this, as well as for his own individual exertions, we owe him a great debt of gratitude. The latest and most distinguishing act which he performed in connection with this compass question was that of making the voyage to Australia and round the world of which we here have the narrative. The ship in which the voyage was made was the Royal Charter, of which little now remains but melancholy memories.

The volume before us comprises three parts. The first consists of an able paper from the pen of the editor, Mr. Archibald Smith, forming an introduction to Dr. Scoresby's remarks. In this introduction the editor sets forth the objects of Dr. Scoresby's inquiries, and then takes up and elucidates the nature of the differences which are well known to have existed between Dr. Scoresby and the Astronomer Royal, and which had reference chiefly to the mathematical, or, to speak more exactly, to the theoretical phases of the compass question. The second part consists of an elementary exposition of magnetical principles, and of the phenomena of magnetism and compass-action and disturbance in iron ships by the rev. doctor. The third part is the journal of the voyage.

In so far as the compass question itself is concerned we shall deal with the results of Dr. Scoresby's voyage in the Royal Charter at another time, and shall therefore avoid the discussion of them here. We must not omit, however, to express our sense of the great ability and admirable spirit manifested in the remarks of Mr. Archibald Smith. The question with which he had to deal was an intricate and difficult one, and therefore required thoroughly scientific treatment; having also been the subject of a warm controversy between the Astronomer Royal and Dr. Scoresby it required impartial as well as careful discussion. In neither respect has the editor failed. His paper, though short, is a very important one, and will have the effect of restricting future controversies, which must occur, to the considerations which are really the subject of dispute—a very necessary thing.

But the volume before us has an interest altogether apart from the question of the magnetism of iron ships. Strange as the assertion may appear, we have found more amusement in this book than in any other which we have read for a long time. Dr. Scoresby appears to have been one of those men who, while great upon some one subject, are small upon almost every other. In magnetical science, and indeed in some other branches of science also, he seems to have been a strong, clear, original thinker. But this volume abundantly proves that in ordinary matters he was of the Lilliputian type. His account of the manner in which he came to embark on board the Royal Charter, and of the arrangements connected with that proceeding, is full of tiny details which no man can peruse with gravity; and throughout the voyage we have glimpses of him which are enough "to shake the midriff of despair with laughter." Seven days after the ship had sailed from Liverpool (on her first voyage) she was found not only to be in bad trim, but also to admit water through her sides and decks with a most pernicious degree of freedom. The captain was sick, and in

doubt whether it were well to put back or not; whereupon the rev. doctor gravely undertakes to "go below into all departments of the passengers," as he puts it, and then report to him the results of his "impressions." The examination occupied an hour—"an hour of the most painful solicitude and sympathy," and the doctor occupies more than a page with a narrative of what he saw—among other things, "wives, children, and young women wet throughout their dress up to the knees, without possibility of drying their petticoats, or benefit from shifting them." One "very interesting looking young person" was "reclining on her bed" in "this very condition," and so forth! In another place we are informed that when the passengers had nothing else to do they sat and chatted—a circumstance which our "doctor of divinity" puts on careful record! On another occasion he tells us that, the evening being warm, "most of the ladies sat upon deck under a cloudy canopy, lightly covered, and chiefly without bonnets." At another time he gives us to understand that, becoming pained at the absence of everything but flying fish, he had a bucket of water drawn from the sea for him; and he records in his journal that on taking up a portion in a glass he discovered "a variety of minute creatures" in it, "generally of the animalculæ size and kind." Again, on drawing near the equator the sun, of course, became nearly vertical; and as an illustration of the fact, the doctor tells us "that the shadows of the ladies, having on a popular wide-brimmed hat" [only conceive a shadow in a popular hat] "were represented by a circular disc," except where "the amply expanding dresses happened to distort the circle by spreading incidentally beyond it." On another page we find this entry:—"A cetaceous animal (which, however, I did not see) was observed at some distance to leeward." But we must not multiply illustrations of the worthy doctor's quasi-scientific jottings! Most of our readers will remember the "elderly gentleman of scientific attainments" who sat in his library writing a philosophical treatise, and who, in the agonies of composition, looked sometimes at the carpet, sometimes at the ceiling, and sometimes at the wall; and when neither carpet, ceiling, nor wall afforded the requisite degree of inspiration, looked out of the window at the very time when Mr. Pickwick happened to be blazing away with his dark lantern in a certain back garden at the interview between his friend Winkle and the lovely Arabella. The scientific gentleman saw most brilliant lights glide through the air, at a short distance above the ground, and almost instantaneously vanish; and he began to consider to what natural causes these appearances were to be assigned. They were not meteors—they were too low; they were not glow-worms—they were too high; they were not will-o'-the-wisps; they were not fire-flies; they were not fireworks; what could they be? On the mysterious light again appearing more brilliant than before—dancing up and down the garden, crossing from side to side, and moving in an orbit as eccentric as comets themselves—the scientific gentleman put on his hat and walked quickly out, determined to investigate the wonderful natural phenomena to the very bottom. None can forget how, in the course of his investigations, he unluckily peeped out of his garden gate, and received upon his head "a gentle tap" from the clenched fist of the sagacious Sammy Weller; or how he afterwards demonstrated in a masterly treatise that the wonderful lights were the effect of electricity, and clearly proved the same by detailing how a flash of fire danced before his eyes when he put his head out of the gate, and how he received a shock which stunned him for a full quarter of an hour afterwards. Well, somehow or other many passages in this journal by poor Dr. Scoresby—notwithstanding his real scientific ability—has brought that elderly gentleman of scientific attainments very strongly to our mind.

Perhaps the good doctor's peculiarities have received a heightened colouring from the singularity of the statements in which he refers to his functions as a clergymen on board the Royal

Charter. He seems to have had a wonderful sense of the importance of his services in this respect. We find him continually offering to preach in all parts of the ship; so much so that the passengers seem to have been driven to great forgetfulness in the matter of responding to his offers. He appears also to have had so strong a sense of the importance of his part of the religious services that he had had several of them entirely to himself before he thought of asking the congregation to take part with him by singing a hymn, and then "the possibility" of their uniting in a song of praise and thanksgiving was "suggested" to him after he "had concluded" a certain service. This is not a subject for us to dwell upon; suffice it to say that his congregations appear to have got a little bored with the worthy doctor, for before the voyage out is ended we find him complaining greatly of the insensibility of his fellow-passengers to his ministrations, and learn that his audience has sometimes dwindled down to two—his wife and her maid! He complains, too, that among us Protestants "not only is no respect paid to the minister's official position, but not unfrequently a less value attached to his judgment, on subjects, it may be, professional and critical, than would generally be conceded to a master in any other profession, such as that of medicine or law." What a pity Dr. Scoresby did not live a few centuries earlier!

He seems, moreover, to have been slighted in other ways on board the Royal Charter. He protested against the passengers shooting "with rifles or other guns" at the "unconscious elegant birds gracefully hovering about our rear," when "there was no chance of obtaining them as specimens for the museum;" but no one seems to have attended to his remonstrances. On another occasion, when a flying-fish was caught and served up for dinner, the good doctor seems to have been put off with a very small share of it, for he tells us that "as far as could be judged from one morsel" it "seemed to be delicate eating." And even with regard to his specific business—that of experimenting upon the compasses of the ship—he did not always meet with the utmost consideration; for several days after they sailed from Falmouth he had to complain that iron-barred sheep-pens, iron-bound trusses of hay, &c., were stowed round about the instruments! Again, on arriving at Melbourne the worthy Doctor was unsuccessful in seeing the bishop and other dignitaries quite as often as he desired, although he was so fortunate (as he does not fail to tell us) as to visit some of the principal public institutions in the city "in Mr. Hart's carriage, and escorted by Judge Barry."

As to the style of Dr. Scoresby's writings in this volume, we may pronounce it wonderful. Mr. Atherton's contributions will have familiarised our readers with something striking in the way of an elevated and complicated style of composition; but we fear Dr. Scoresby will carry off the palm even from him. Here, for example, is a specimen passage—written on the arrival of the Royal Charter in southern latitudes:—

"To us, inhabitants in previous life of northern latitudes, a new phenomenon broke strikingly on our attention, viz., the appearance of the sun performing its daytime progress to the northward, with the astronomical peculiarity of meridian observations being taken with the face of the observed turned towards the Arctic pole!"

In another place—to take a second example—he explains the vibration of the stern of the ship in the following manner:—

"The disadvantage was ascribed to the fact of the direct action of the engine with nothing of intermediate and yielding contacts to break the force of incongruous contacts and operation of the water. The effect was often such as to cause the ship perceptibly to shake in the manner of an elastic flexure as, apparently to sensation, of some inches up and down, giving correspondent vibration in the spanker boom, as supported at the two ends, amounting to a spring-like movement of the intermediate timber up and down."

But there are, even in the "journal" before us,

facts of more or less value which we purpose extracting for the benefit of our readers on a future occasion.

Patents for Inventions. Abridgment of Specifications relating to Electricity and Magnetism, their Generation and Applications. Printed by order of the Commissioners of Patents. London: Great Seal Patent Office. 1859.

We have here the most bulky, and perhaps the most important, of that series of abridged specifications of patents which the Commissioners of Patents are so wisely publishing. It comprises no less than 830 pages, and contains short descriptions of all the inventions ever patented in connection with electricity and magnetism, together with a summary of the progress of knowledge in reference to them up to the time of the commencement of the patents. The summary also embraces any discoveries, inventions, or applications that are not treated of in the body of the work, at whatever date they may have been invented or brought into use. We are not, however, we must honestly confess, perfectly satisfied with the manner in which this volume has been edited. Very many of the abridgments are much too long—much longer, that is, than they need have been to answer their purpose, and to stand side by side with those put forth in previous volumes. We observe one abstract occupying very nearly ten pages, and three and four pages are frequently occupied with single patents. The consequence is the volume costs a considerable price—*2s. 6d.* Such lengths are altogether unnecessary for the purpose of these volumes of abridgments, which can never serve of themselves any other object than that of acquainting readers in a general way with the nature of the inventions. We also observe that the editor has made either more or fewer verbal emendations than were necessary. It seems to us to be a little pedantic to make formal corrections of small and manifest misprints, and yet to find one word spelt in four different ways without corrections ("gimble," "gimboal," "gimbal," "gimbol"). But notwithstanding these small faults, we cordially accept this book from the Commissioners of Patents. They are doing a great and valuable work in issuing these and their other publications, and if they would only give us a proper library to consult them in, we should be doubly grateful to them.

An Elementary Treatise on Logarithms, illustrated by carefully selected examples. By the Rev. W. H. JOHNSON, M.A., Assistant Professor of Mathematics at the Royal Indian Military College, Addiscombe. London: Longman, Green, Longman, and Roberts. 1859.

As this little work answers faithfully to the author's intention, we need do no more than repeat what he tells us in his preface. We there learn that the "recent introduction of logarithms into the test required for admission to Addiscombe has induced the author to publish the following treatise. It will be found useful, he hopes, not only to those who are seeking to enter the Royal Indian College, but also to those who intend to continue, or complete, their mathematical studies. The body of the work will be sufficient for students who wish to acquire merely the power of applying logarithms to arithmetical operations. The appendices, at the end, are added for those who are desirous of learning the process of constructing logarithms. For the understanding of the entire work no more previous mathematical knowledge is demanded than that of arithmetic and the first principles of algebra. It is perhaps unnecessary to say there is no pretence of novelty in the proofs; but the author trusts that he has arranged the subject clearly and methodically, and that he has succeeded in furnishing a serviceable and a sufficiently copious set of examples, about the accuracy of which the utmost care has been taken, and to which there are given proper forms

according to which the student may work. The advantage, indeed, of cultivating a neat and connected style of writing out logarithmic calculations cannot be too early insisted on. It will be readily admitted by all who have been engaged either in teaching or in examining. The plan adopted in these pages is one that has been recommended by a practical acquaintance with its usefulness."

NON-INFLAMMABLE FABRICS.

It is but seldom we have the privilege of addressing the fair sex upon a subject exclusively regarding itself, and those who are most interested in its welfare. Science, which benefits the ladies indirectly, can seldom claim a peculiar interest on their part for any of its wondrous processes and beneficial results. Indeed, were it not for the brilliant fabrics and multifarious contrivances solely intended to minister to their taste, and to a desire to please which cannot be too highly appreciated, they might almost accuse science of neglect. But every spring and every autumn the manufacturer delights in offering new and delicate products of the loom—the freshest and richest nuances of colour—at the shrine of beauty, which seeks his aid for its adornment. This aid may not be wholly disinterested—no more, perhaps, than the amiable desire to please to which we have alluded; but it is not now our duty to inquire too closely into the hidden motives and mainsprings which regulate the actions both of women and of men. There is however one omission on the part of the manufacturer which, if not hitherto culpable, proves that his desire to please is not allied with a sincere regard for the safety as well as for the appearance of his *fais pratiques*. In supplying them with muslin and with gauze, which, like the new foliage, hail the advent of summer, and flutter in the tepid southern winds, he forgets to label his gossamer wares with the warning "dangerous," which accompanies less destructive and less fatal products of the druggist's shop. And yet one second's contact with flame, the wafting of the fairy robe towards candle or fire, inevitably envelops its wearer with the devouring element, and exposes her to a terrible death or to fearful disfigurement. Arrayed in such materials, she is surrounded with danger against which no protection can avail; the merest chance, the commonest accident, is sufficient to occasion a sudden and horrible fatality for which there is seldom help or remedy.

We have no need to advert to occurrences of which the lamentable details are familiar to all, and by which some of our brightest and fairest have been removed from our midst, in order to insist upon the necessity for some adequate safeguard against the danger in question. Many a household can tell of casualties which, if they have not been fatal, were the cause of suffering and terror, mingled with thankfulness that a heavier calamity, which had been fully incurred, was yet escaped. But it is now in the power of every one to banish such danger from the list of contingencies to which every household is liable; and it is our cheerful task to point out the means which have been placed at our disposal to secure the safety of those who claim our interest, and have a right to our protection. The practicability and efficiency of these means have already been tested on a large scale; and it is confidently anticipated that they will be adopted by all, being attended with little or no sacrifice of time, money, or appearance.

It has long been known that a material of cotton or thread could be in great measure preserved from the effects of flame by soaking in a

solution of alum, or common salt. The expedient is a simple one; but in practice is liable to objections which, more than any wilful disregard or carelessness, have prevented its general employment. The fabric which is soaked in common salt becomes crisp and harsh to the touch; while that which is saturated with alum is seriously injured by the process, losing its strength by reason of the action of the salt upon the fibre. The chemist was therefore called upon to discover a substitute which would exert no injurious effect upon the colour, the appearance, or the strength of the material to be rendered non-inflammable. The investigation—one of considerable research and some difficulty—was undertaken by Messrs. Versmann and Oppenheim, to whom the thanks of the ladies are due for a long series of experiments made in their behalf. It was found that borax exerted a powerful preservative effect; but that the combination of the chemical ingredient impaired, in some degree, the strength of the material operated upon. The effect of more than forty different salts was then tested in the laboratory, the Royal Laundry, and various muslin manufactories; and a re-agent was at length discovered answering in every respect the requirements of the manufacturer; who, it is to be observed, finishes his muslins without the application of a hot iron. But more was yet required of the chemist. The amount of the re-agent in question, viz., the phosphate of ammonia, required for a perfect preservative effect, was very considerable; and, moreover, the salt decomposes under the iron of the laundress, rendering the operation of ironing after its employment a matter of some difficulty. The sulphate of ammonia, a salt only one-fourth the price of the phosphate, was found advantageously to replace the latter for the purposes of the manufacturer; a similar preservative action being obtained with a much smaller amount of the re-agent. Both salts, however, are soluble in water, requiring renewal after washing; and both are liable to the same objection with regard to the ironing process. A substance was therefore required to answer a domestic purpose, and which, while allowing the hot iron to pass smoothly over the surface of the prepared material, would afford a perfect guarantee against the effects of flame, without injuring in any degree the strength or appearance of the fabric. A salt fulfilling these conditions was ultimately discovered by the above-mentioned chemists in the *tungstate of soda*. This salt is now in constant use in Her Majesty's laundry at Richmond; and it is to be hoped that its application may quickly become general. It remains only for the wearers of light summer fabrics to require that their goods shall have undergone the preparation through which their wearers will be preserved from the dangers resulting from accidental ignition, and that the laundress also shall employ the *tungstate* solution of the domestic difficulty in obtaining the same desirable result of safety against fire.

ON THE FURTHER ADAPTATION OF THE COINAGE TO THE COMMON NUMERICAL SCALE.

By JOHN TORRIS, M.A., LL.D., Serjeant at Law, Senior Fellow of Gonville and Caius College.

TO THE RIGHT HONOURABLE THE CHANCELLOR OF THE EXCHEQUER.

SIR,—The final report made by two members of the Royal Commission which has considered "the practicability and expediency of introducing the decimal principle into the coinage of this country, without contemplating any change in our present system of weights and measures, and without considering the possibility or advantage of an international system of coinage," although, as to one particular scheme it concludes, that "it is not a well-assured or demonstrated improvement on our present coinage," will probably lead to the conviction that the assimilation of our coinage to the common numerical scale which was begun by the issue of the florin must now proceed; and this conviction will be the stronger as the questions

put to the witnesses by Lord Overstone, one of the commissioners, seem to raise all the objections that can be made to decimal systems, and show an entire freedom from prejudice in favour of any of them.

The problem now to be solved is:—

How to take the next step toward obtaining a superior coinage, so as to avoid transitional difficulties, and yet obtain a coinage which agrees, for purposes of account, with the common numerical scale, and which in its other conveniences is not inferior to the present coinage.

It is the solution of this problem which I here attempt.

The fact that the base of the common numerical system has but two factors, affords the principal argument against extending its use, and although some conveniences are alleged to attach to the binary scale, I believe it may be assumed that if the base of the numerical system were 12, coins, weights, and measures, would, by common consent, be adapted to that system.

A sound distinction has been adopted by the commissioners, in treating the purposes to which coinage is applied, as separable into two classes; and coins as they are applicable to the purposes of these two respective classes may conveniently be called Coins of Account and Chandlers' Coins.

Coins of account, to be good, must necessarily agree with the common numerical scale, that is, they must be decimal.

Chandlers' coins, to be good, must adopt a base which has, or bases which have, the greatest number of factors that any number not greater than this base, or the product of those bases, can have. It is not an essential merit in chandlers' coins to be decimal, but it is a collateral merit, because it makes them coins of account.

If 12 were the base of the numerical system, chandlers' coins and coins of account would be identical. The advocates of decimals may, I believe, concede that to have a good chandlers' system is as important as to have a good system of account, or more so.

The merit of our present system, as a chandlers' system, consists in its having the factors 2, 3, 4, 6 between the penny and the shilling, and the factor 5 between the shilling and the £; but it is a defect to have the factor 4 encumbering this 5, and making the product of the bases 240. The Austrian system of florin and kreutzer is superior, as it introduces 2, 3, 4, 5, and 6 in the smaller number 60.

I leave the cabalistic symmetry of 1×4 , 3×4 , 5×4 (Report, p. 27) to be worshipped with that of the seven planets and the seven perfect metals, to which it seems analogous.

Referring to what has been already done towards obtaining a good coinage of account, it appears that

The £ has been taken as the maximum unit.

The florin has been based upon it, and the House of Commons has resolved,

"That the initiation of a decimal system by the issue of the florin has been eminently successful and satisfactory," and

"That a further extension of the system will be of public advantage."

Further, it has, I think, been sufficiently established by experience, that:—

"The universal law of all decimal coinages is to reduce themselves to two coins of account only, the one being 100 times the value of the other." Report, p. 10.

It follows therefore that if the cent, or $\frac{1}{100}$ part of a sovereign be added to the present coinage, the coinage of account will be complete.

Turning now to the chandlers' coinage, this assumption seems to be warranted:

All the advantages of a good coinage of account may be obtained, although some coins that do not belong to the system are retained as chandlers' coins.

This proposition appears not to be admitted, when such facts as the following are found among the arguments that have delayed the adoption of a good system of account:—

"The decime has never succeeded in supplanting the sous in retail transactions, although for all important calculations the franc and centime notation has become universal." Report, p. 9.

At New York the price of a bottle of beer was called three shillings, although it was inserted in the bill as 37 cents: and generally throughout America although prices are expressed in cents, the number of cents employed shows that coins are still in use that do not belong to the decimal system. Kelland, Report, p. 13.

I assume, however, that the introduction of a good coinage of account is complete, when its notation is used "for all important calculations" and for lists of prices and tavern bills; although the word sous may still be used for five cents, and the confusions of American coinage may not entirely disappear for ages; and that as decimal coinage does in fact make its way steadily and without recoil, its ultimate adoption is certain, although that adoption may never put out of use such words as sous and shilling.

If the object were simply to obtain a good chandlers' coinage, it would be necessary to consider whether it would do to leave the cent to be subdivided into binary fractions, to which it would have, in the opinion of the commissioners, a natural tendency (Report, p. 10); there are, however, the difficulties of transition to be surmounted, and to meet these I think that—

The penny must be retained.

I propose, then, to coin a mite in value 1/16th of a penny, and as the cent would contain 12 mites, the coins of account and the chandlers' coins would be connected, and every existing coin could be retained excepting the halfpenny and the farthing and even these would be current when they made up pence.

It has been objected to the £ and cent as coins of account, that the cent is too large for a minimum. Bankers at present use a penny, and Professor Kelland says, Report, p. 28:—"It is only by the universal consent of their customers that they are now able to neglect sums less than a penny, not merely in the totals of their accounts, but in every single bill of exchange or other separate item. It is impossible to guess when a similar agreement would be come to with reference to a new minimum."

I believe that this is erroneous, and that a banker consents to borrow the money, and to transact the business of his customer, on the condition that he shall not be troubled with small fractions, and whether 1 or 5 cents became the minimum would be decided by bankers themselves.

The minimum chandlers' coin would be the mite, and it would, as far as magnitude is concerned, be neither better nor worse than the farthing; it would divide the penny by 5 only, but the cent by 2, 3, 4, 6; and, therefore, unless the value of this property has been overrated, it would be a better chandlers' coin than the farthing.

A half cent would, I think, be an essential coin.

The coinage would then stand:—

COINS OF ACCOUNT.

The £ and the cent only.

COINS IN THE DECIMAL SCALE.

	Cents.
£	100
Florin	10
Shilling	5
Sixpence	2½
Threepence	1½
Cent	1
½ cent	½

THE ENTIRE OR CHANDLERS' COINAGE.

	Cents.	Mites.
£	100	
Florin	10	
Shilling	5	
Sixpence	2	6
Fourpence	1	8
Threepence	1	3
Cent	1	
½ cent		6
Penny		5
Mite		1

The fourpence, the threepence, and the sixpence should be allowed to disappear as soon as convenient, and ultimately the penny also; leaving the decimal scale composed of

£, florin, shilling, cent, and half-cent; to which the chandlers' scale would only add the mite.

The mite is used, principally, as a coin of transition; it enables the penny to exist in conjunction with the decimal coins. The additional experience which the use of these coins afforded would decide whether the mite should be permanently retained. When it had discharged its function of introducing the cent without disturbance to existing habits, it might be withdrawn, and the mil substituted; a complete decimal system would thus be obtained.

To recapitulate: I propose that a cent and a mite be coined forthwith, and that public accounts be henceforth kept in the £ and cent.

That as soon as expedient a half-cent stamp be substituted for the penny one.

No coin need be actually withdrawn, but the farthing, halfpenny, threepenny, fourpenny, and sixpenny should disappear as soon as convenient; and there should be no new issue of the penny.

To make a bronze cent of a convenient size would be a problem worth the best attention of the metallurgist; a silver cent would for size be neither more nor less convenient than a threepenny piece.

The extension of the common numerical scale to weights and measures will result from the operation of the causes which lead to its adoption in the monetary system, but will not be a consequence of that adoption, nor necessarily connected with it.

The Report truly states that the weight of scientific authority is in favour of the projected change in the coinage. It is undervaluing the authority of one of those who favour the change to call it simply scientific; the rare power of estimating the wants of non-scientific minds and of bringing the truths of science within their reach, gives to the opinion of one who so eminently possesses it a weight incomparably above that of mere scientific authority.

The Report states also that there is an indifference to the change among commercial classes; the change appeals to the reason and the judgment, and will, therefore, never enlist enthusiasm in its favour. Commercial men have moreover the habit of using the present system, or they employ those who have; there is nothing to force on their attention the advantages of a simpler one.

Give the value of $x + x^2 + x + x^4$ when $x = 11\frac{1}{4}$ d., and find the square of £19 19s. 11½d., are to be found among educational questions propounded during the present century; and they might be restored to their place as such without exciting indignation at Lloyd's.

There is, however, a class neither scientific nor commercial; it consists of men whose education gives them a clear conception of the advantages of the decimal system; and one of this class who has not the mechanical skill which a commercial clerk can acquire, nor the trick of memory which a calculating prodigy possesses, winds through the clumsy complication of a column marked £ s. d. with a feeling that the occupation is a degrading one.

The coinages with which the issue of the cent would establish a community appear to be those of Venetian Lombardy, Austria, Holland, Prussia, and France, the franc being, very nearly, four cents.

I am, Sir,

Your most obedient and most humble servant,

JOHN TOZER.

3 Inner Temple-lane, 18th Oct., 1859.

A letter from Alexandria says:—"The laying down of the electric telegraph between Suez and Aden has, in spite of bad weather, been accomplished by the Cyclops. From Aden the electric wires are to be carried to Schugra, then through Hadramant, a province of Southern Arabia, then to the isle of Socotra, at 250 miles from the Straits of Babel Mandeb, and then by the isle of Ceylon and the Gulf of Bengal to Calcutta. When the line shall become completed, the total length of cable submerged will be 3,750 miles.

UNSINKABLE SHIPS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Woolwich Dockyard, 8th November, 1859.

GENTLEMEN,—My letter on unsinkable ships in the Society of Arts' Journal of the 28th ult., and your editorial article thereon in your last week's number (No. 45), have already attracted the attention of inventors with a view to the production of materials suitable for the purpose to which I have alluded, viz., the construction of unsinkable ships; and from the nature of the communications which I have received you will do me a favour, and some of your inventive readers a service, by inserting in your Magazine my letter of the 11th ult. in full as it appeared in the Society of Arts' Journal, excepting that I will thank you to place the two extracts from the Times in juxtaposition. There is no part of your editorial critique to which I object, although evidently intended to overrule my suggestion. The great use of publicity is to draw the attention of thinking men to the subject that may be referred to, and as all your readers are of a class who think for themselves, I am satisfied that only good can result from any latitude of expression or forced construction of my views on which, as in some respects in this case, you may be enabled to advance some sound and useful views of your own. The practicability of the principle of my suggestion, namely, that ships may be made unsinkable, however perforated by shot, will, I have no doubt, be conceded; but the extent to which the adoption of this principle can be advantageously carried will greatly depend on the properties of the material that may be brought forward, including the few properties that I have enumerated to exemplify my views, and many others, such, for example, as being fire-proof, which it is hoped may be effected now that many preparations have been devised for rendering even wood unflammable. The comparative expense of such unsinkable ships with reference to any other known mode of preventing accidental foundering, and setting Armstrong's ordnance and, I may add, the contemplated Nasmyth steam ram, at defiance so far as the absolute sinking of such ships is concerned, is essentially dependent on the success that may attend the inquiries now proposed to be set on foot, combined with the plans that may be devised for the application of such material to the construction of floating bodies, whether intended for the purposes of commerce or of war. And here again, as you truly, though rather sarcastically, observe, is a subject for the exercise of inventors "worth a very handsome premium, and the Society of Arts would do well to offer one for it before they offer the other." I concur in this your recommendation to the Council of the Society of Arts, only I would prefer that the required material possessing in the highest degree the properties of specific lightness, toughness, non-absorption of water, cheapness, unflammability, &c., &c., &c., be determined upon before the premium for its application to the purposes of naval architecture be offered; also, as another preparatory step, I would suggest for consideration this question—Where is this premium to come from? On which point I may observe, that if improvement in modern ordnance necessitated the introduction of iron-cased ships of war such as the Trusty, and if further improvements, such as the Armstrong gun, firing elongated bolts of malleable iron or steel, has already rendered iron-cased ships of the Trusty class no longer trustworthy, but necessitated further improvement in the hope of defying even the Armstrong system of ordnance; as, moreover, the steam ram is looming in the distance, and as it is difficult to see any end to this rivalry of gunnery and rams versus iron-cased ships, or of the cost that it will involve, I would merely suggest that if for every one million of money thus devoted by Parliament to the construction of iron-cased shipping with a view to invulnerability, £100 only were awarded as a premium to naval architecture, with a view to promoting the efficiency of unsinkable ships of all classes respectively, it is probable that such rivalry between modern intellect and

modern ordnance would be conducive to public good and to the peace of the world. For my part I would have little doubt of Britain being at peace with all the world if all ships were effective for their respective uses and unsinkable. Pertinent to this subject it may not be out of place that I here refer to a noble sentiment of Admiral the Earl of Dundonald. It was my official duty in January, 1848, to test the performance of the *Hanshee*, a vessel built by Government expressly for the service. On my return from the trial, I found Admiral the Earl of Dundonald at Woolwich Dockyard; I told him of the unprecedented steaming speed we had attained, namely, 16 knots per hour. The noble Admiral replied: "Had I the command of such a ship in war, I would not encumber myself with guns—I would run up to and board everything I could catch." Various essentials to the realisation of this noble sentiment, so characteristic of the man, are obvious; an unsinkable ship with machinery invulnerably cased in, the crew protected from the *Minie*, and commanded by a Dundonald (and a thousand such men will be forthcoming when required), would be an ugly customer, I guess. But it is not my purpose at present to go into any details of naval architectural construction in connection with unsinkable ships. I will merely observe that the property of being unsinkable does not necessarily imply that such vessels shall have no stowage below the level of the load water line which may be appropriated to machinery; and I may further remark that, by the construction of line-of-battle ships, such as the *Royal Albert*, only about one-third of the internal cubical capacity of the ship is below the level of the load water line.

In the conclusion of your critique you respectfully invite me to tell you what I am thinking of, and I as respectfully reply that since the introduction of iron cased ships, and especially since the reported practice on the *Trusty*, I have been occasionally thinking how ships of all classes respectively may be rendered unsinkable compatibly with the respective uses for which they may be designed; and this is the subject on which I now hope to interest the Council of the Society of Arts, and through them, and by the aid of the Society of Arts' *Journal*, and with the co-operation of the *MECHANICS' MAGAZINE* and other publications usefully devoted to such inquiries, I hope to interest the public. I am, Gentlemen,

Yours very obediently,

CHARLES ATHERTON.

THE GREAT EASTERN AND STEAM SHIP ECONOMY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Mr. Atherton has been so obliging as to favour us with his views on the above subject in reference to some remarks of my own, and he includes a slight notice of the doubt I expressed in my last communication, as to the appropriateness of the formula $\frac{V^3 D^3}{\text{Ind. h. p.}}$ for determining the dynamic performances of the Great Eastern and of the mercantile marine generally.

In order to come to a clear understanding on the suitable application of formula to this vessel, we must divest the subject of some extraneous considerations to which Mr. Atherton has adverted, although proper enough in their place.

Now, it is the performance of the Great Eastern as a ship, in the two aspects of velocity alone and conjointly with burthen, and as being the result of a definite amount of indicated horse-power, that we have to investigate, and not any merit in the engines and boilers. It is with the scientific application of the power as provided, and not with any development thereof, that we have to do. The formula $\frac{V^3 D^3}{\text{Wt. of coal.}}$ must therefore be

put aside as irrelevant, however useful in other respects. I must, however, remark by the way, that it will ever be vitiated by the factor D^3 , if that factor be, as I apprehend, a misleading

quantity. Equally irrelevant to the commercial excellence of the vessel is the point of recouling only at the end of the voyage. That solely concerns the commercial *management*, and though put forward as a desideratum, will, I hope, be found otherwise, through a more valuable freight than coal being secured.

The point, then, exclusively for discussion is that which Mr. Atherton says is the subject of his Table No. 2, "showing the superior capability of large ships, as indicated by the progressively reduced ratio of power to a progressively increased displacement, the speed being constant," and requiring for decision the horse-power as declared by the indicator. In what degree this superiority belongs to the Great Eastern will be satisfactorily determined only when she is deeper in the water than at present, until which time it will perhaps be better to wait; but it is clear from the very nature of the subject, and from these Mr. Atherton's own views of it, that her merits must necessarily be equally pre-eminent with her size, unless there is some awkward circumstance in her build sufficient to neutralise all advantages. Her lines are admitted to be good, but Mr. Atherton thinks unfavourably of her small draught in proportion to breadth. I confess my incompetency to give an opinion on this point, it is so much a question of compromise to be dealt with by the practical man alone, but I must say I should be surprised if it were proved that anything in this circumstance adverse to her performance is not fully compensated by her small breadth in proportion to length, thus having the balance due to capacity untouched. I think, indeed, it would be surprising if it were not far more than compensated, when the great depth to which otherwise she would have been immersed is considered, and the great resistance opposed to the translation of water at such a depth. Mr. Atherton brings down the performance of the Great Eastern to the rather low co-efficient 200, but then he gets at the horse-power, not by means of the indicator, but through the consumption of coals, which is unfair to the ship. Besides, the datum of $3\frac{1}{2}$ lbs. per indicated horse-power per hour is only a loose estimate.

It was, however, to what I conceive to be a radical fault in the formula used by Mr. Atherton, that I wished to draw his attention—whether my proposed correction told favourably or otherwise on the merits of the Great Eastern. Am I to understand that he maintains the appropriateness of that formula, or even indeed its correctness, relatively to its ostensible purpose? or will he acknowledge with me, that the simple displacement would be a better factor than any power thereof? It would in this form be a much more satisfactory criterion of the merits of a ship, in the matter of size and build purely as a scientific construction for a mercantile purpose, and yet for a criterion of practical commercial excellence it would be nearer the truth to take the actual weight of the cargo, by which any peculiarities of construction, such as cellular sides and the like, would be eliminated. But in respect to the formula as it at present stands, will any one speak up for it? In addition to what I have already said, let me ask—what is it that is intended to be expressed? Is it not the power on one side and the effect on the other? But if the entire effect was what is referred to, these quantities would be always equal to each other. It is the useful effect, then, that is meant, and this being divided by the power, gives us the comparative worth of our contrivances for utilizing it as much as we can. Now, what is the useful effect in the present case? It consists in opening out a passage in the water; its positive value depending both on the extent and the velocity with which it is effected, and its comparative value in the dividing and translating of the water, with the least possible velocity given to the least possible number of its particles. Well, then, what need we else for the factors that are to express the useful effect, but the quantities that constitute it—velocity and displacement? The latter term

should fix on the mathematical mind the work done in the water, and not technically the corresponding property of the ship. It is true we cannot apportion the work between the useful and the useless, or express either in terms of force and motion; but the useful effect is sufficiently tangible to be measured in a way to serve the purpose of comparison, and therefore cubic feet would stand as well as tons for the displacement. It is of course necessary that the cube of the velocity should be taken; but what does the power of the displacement mean? We see that looking at the physics of the subject in the water, we must either take this factor as it is, or discard it altogether, and accept the midship section instead thereof. Perhaps, however, it means this, that it does duty for the midship section—a false fictitious thing instead of the real. In that case, perfect or imperfect, we wander from the effect to the means; we lose sight of burthen altogether, and velocity alone comes to be considered as the useful effect. This limitation is indeed very desirable when we wish to take the comparative worth of the lines simply of different vessels, and the corresponding formula is very appropriate for the Royal Navy, or for more passenger vessels. But a factor avowedly standing for the midship section is one thing, and a factor virtually representing it, and labelled otherwise, is another thing with another character. The formula in which it stands does not present an honest face; it talks of tonnage and displacement, and makes believe to be a true servitor of solid commercial interests, but under the guise of their own livery, slips away from his charge to run after other masters of the skip-jack race, serving them, by the bye, in the most slovenly manner withal.

I cannot in conclusion refrain from observing—but without any allusion to Mr. Atherton, who, as I understand, is not the author of this objectionable formula—that it certainly justifies to its own extent the animadversions I have often committed to your pages, concerning the frequent deficiency in mixed mathematics of a clear and sound understanding of the physics involved in the subject investigated, by which pompous nothings are enabled to gain, through a mathematical dress, a prestige which they do not deserve.

Yours, &c., BENJAMIN CHEVERTON.

THE INVENTION OF THE SCREW PROPELLER.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Having read in your last week's paper a very interesting account of the invention of a screw propeller by George Blencowe, which I think may not improbably have been the real origin of the one now in general use, I venture to send you a short notice of another inventor, whose discoveries were made a little earlier in time, but were not successful in obtaining any public recognition after their first trial.

Between the years 1821 and 1828, Mr. James Wilson, of Patrie-st (subsequently acting-manager to Mr. Nasmyth) made numerous experiments with a view to the construction of a screw propeller for ocean navigation. After many trials, he completed a small model (fitted with both paddle and screw-propellers), which was tried with perfect success at Leith in 1828, in the presence of Mr. Hunter, of Thurston, and other gentlemen well versed in mechanical pursuits. The result was a request from the Highland Society of Edinburgh for a more complete series of experiments on a larger scale, together with the grant of a small sum of money from the Society in aid of Mr. Wilson's undertaking. The first experiments were made on March 10, 1828, and subsequently in April of the same year, and a full report published on May 4th, 1828, by the sub-committee appointed by the Society to witness them, in which it is stated that a boat eighteen feet long had been constructed, and fully tried in the open sea outside the pier at Leith, in a very heavy sea and a stiff N.N.E. breeze, in the presence of Admiral Sir David Milne, Captains Roswell and

RICHARDSON AND JAFFREY'S IMPROVED BREAKWATER.

FIG. 1.

FIG. 2.

Trotter, R.N., and others, and that in the opinion of these gentlemen it had proved entirely successful, the impetus communicated by the propellers at the stern having been much greater than that which could have been given by oars, while the resistance offered to heavy seas on the boat's quarter was also much less.

The model made by Mr. Wilson was deposited in the rooms of the Highland Society, and was destroyed by fire a few years ago when their museum was burnt. Another, but I believe smaller one, is still preserved at Thurston House, near Dunbar, where it has remained for more than thirty years since the late Mr. Hunter first encouraged Mr. Wilson to proceed with his experiments. I believe that Mr. Wilson is about to publish a detailed account of his plans, from which it will clearly appear to what extent he is entitled to claim the invention of the screw propeller. I am, Gentlemen,

Your obedient servant,

W. S. W. VAUX.

British Museum, November 7, 1859.

RICHARDSON AND JAFFREY'S IMPROVED BREAKWATERS.

Messrs. THOMAS RICHARDSON and G. W. Jaffrey, engineers, Durham, have just completed a patent for an invention which relates to the arrangement and construction of defensive and protective sea works of various kinds, such as harbours of refuge, breakwaters, sea-walls, barriers, and other sea-board structures or contrivances intended either for the defence of the coast against the action of the wind and waves or for protecting shipping. Fig. 1 of the annexed engravings represents in side elevation and partial vertical section a breakwater constructed according to this invention, and Fig. 2 is a corresponding plan and horizontal section of the same. In carrying out the invention in the arrangement and construction of a harbour of refuge for ships the patentees, in the first place, construct a number or series of iron towers *A A*, so that when these towers are deposited in the sea at the predetermined distance asunder, they extend outwards and partially enclose the required extent of sea room. The towers are by preference made of a circular figure in transverse section, wide at the base and tapering towards the upper part, sweeping inwards from the base with a curve, or rising upwards with straight sides of a gradually tapering or conical figure. These towers are by preference constructed of cast-iron or malleable iron, or partly of both kinds of metal, but in lieu of these materials they may be constructed of stone or timber, and made solid in the manner hereinafter described. In constructing the towers of metal a framing of perpendicular and transverse circular or cylindrical ribs is bolted together so as to form

a skeleton figure of the predetermined shape. This framing is then covered with sheets of cast or wrought-iron, which are riveted or otherwise secured to the internal framing. "The height and size of these towers must depend," say the patentees, "to a great extent upon the depth of water and the position of the work; we may, however, give as an example of a useful size for these towers diameter at the base thirty-five feet, tapering to a diameter of twenty-seven feet at the upper part. The open bottom towers constructed in this manner are taken out to sea in succession upon a powerful derrick or pontoon, or other suitable floating apparatus, and are then sunk upon the spot required; the towers are arranged in a straight or curved line at such a distance apart as to leave between each an intermediate space equal at the upper part to the smaller diameter of the tower or thereabouts. The towers being disposed in this manner, the water contained within each is then pumped out, and the interior of the tower is filled in with masonry, the blocks of stone being previously cut to the required shape on shore; in this manner the work may be carried on with great rapidity, the cement used in the building operations being meanwhile wholly protected from the wash of the sea water. Instead of using stone as the material for filling in the towers, concrete, beton, or other hard drying plastic cement may be moulded into blocks of the required figure on shore and dried; these blocks when fitted into their proper places within the tower are to be cemented together with a thin mixture of the cement or plastic material used for moulding the blocks. In some cases we should give the preference to another mode of procedure, namely, to fill the whole of the interior of each tower with 'beton' or hydraulic cement, as shown at *B*, which cement solidifying within the tower, the whole forms a compact and solid mass capable of withstanding the waves of the sea after the removal or wearing away of the external plates of metal. In lieu of this solid mass of beton, a filling-in may be used composed of beton, having a central mass or core of slag as at *C*, the interstices of which may be filled up with the liquid, so as to form the whole into a solid mass. The operation of filling up the towers with masonry or with plastic materials is materially facilitated by the convenience which the summits of the towers afford for at once laying down a permanent gangway or road *D* from one tower to another, along which gangway materials and implements can be conveyed with nearly the same facility as on shore. In this manner the expensive and costly plant required in harbour and coast works of the ordinary kind are wholly dispensed with, and the work is done at far less cost than can be accomplished with the usual structures. In place of constructing the towers of iron, they may be built wholly of stone, a suitable

caisson being sunk over the spot where the tower is to be erected; the water having been pumped out of the caisson, the work may be carried on with great rapidity if the several blocks of stone have been previously cut to the required shape on shore. The open spaces between the contiguous towers are filled in with open vertical frames *E E*, which serve to break up and divide the waves as they roll in, the water passing through the open screens without hindrance, and yet in a comparatively smooth and untroubled state, and so as to render the position of the shipping in the harbour perfectly secure. These lattice screens are constructed of barks of timber strongly bolted together, open rectangular spaces being left between the contiguous vertical and transverse beams of timbers. These lattice screens are by preference constructed on shore, and in the opposite faces of such contiguous pair of towers, a deep vertical groove is formed, either by bolting pieces of angle iron to the face of the tower, or by casting the grooves in the plates of towers, or by securing pieces of timber thereto in a similar manner. These lattice screens are taken out in succession on the derrick, they are raised thereby to a sufficient height to admit of their being lowered down into the grooves made for their reception on the contiguous faces of the towers. Another mode of constructing these screens is to form them of cast-iron pipes or of malleable iron tubes. The vertical tubes are connected together so as to form a frame or lattice by means of transverse bars of metal at the upper and lower parts, and, if necessary, at intermediate distances. These screens are fitted into the adjacent grooves in the towers in the same manner as described in reference to those composed of timber. In addition to the protective action of these screens there is another and highly important advantage attending the use of them in harbour and other similar sea works, which is, that from their open construction they prevent the silting up or accumulation of the sand inside the harbour, as the tide has free access and egress through the open screen, so that the original depth of water is maintained, and a prolific source of expense in the maintenance of dredging apparatus is avoided. The construction of harbours, piers, or quays upon this plan admits of vessels approaching close up to the towers, thus avoiding the waste of room and inconvenience attending long sloping sea-walls of the ordinary construction. Even in situations where a rigid or impermeable sea-wall would not be objectionable, our system offers considerable advantages in point of strength, economy of first cost, and facility of construction. In such situations the towers are constructed and disposed as hereinbefore described, but the intermediate spaces between the towers are filled in either with a wall of masonry as at *F F*, or are formed of blocks of 'beton' or concrete cemented together, and

CLARK'S APPARATUS FOR HEATING FEED-WATER.

defended or not on the outer or seaward side by a lattice-work of timber or metal. For these structures the towers may either be the simple iron tower sunk into its proper place, or it may be partially or wholly filled up with masonry, 'beton,' or other suitable material. According to this system of constructing harbours, breakwaters, sea-walls, and other similar exposed works, it is impossible to carry out such works in a manner more economical, for if properly conducted no portion of the materials employed need be wasted, which is far from being the case in structures of the ordinary kind, however careful the contractors may be in the disposal of their materials."

CLARK'S APPARATUS FOR HEATING FEED-WATER.

MR. DANIEL KINNAR CLARK, the well-known writer on railway machinery, has patented for the above purpose an invention of which he gives the following description:—

The invention consists in a simple and compact method of heating the feed-water of steam-boilers by the forcible and immediate intermixture of currents or jets of water and steam brought into direct contact and travelling together, as follows:—One or more jets of steam are discharged freely and directly through a pipe or other passage or chamber of suitable form, into which also the water to be heated is delivered, and through which it is passed in conjunction with the steam; in this confined passage the steam, in virtue of its initial velocity, forcibly impinges upon, mixes with, and disperses the water, and is quickly condensed, and the water is proportionally raised in temperature by the heat of the condensed steam. When more than one jet of steam is used, the jets may be placed side by side, or they may be placed in succession. When the heating apparatus is above the level of the source of water supply, the water may be raised to it by pumps or other external means. The jet of steam is so adjusted as by suction to draw and conduct the water into and through the heating passage, thereby assisting and, if powerful enough, superseding the use of external means for lifting the water. The jet

nozzle may be contracted at the orifice to sharpen the blast. The water may be delivered round or within the jet of steam, which in the latter case is annular, or there may be a series of jets in a circle.

The heated water passes freely from the apparatus, and may be either pumped directly into the boiler or reserved for use. A free vent is provided for uncondensed steam. The supply of steam may be taken from the boiler direct, or from the exhaust passages of steam engines connected therewith, whether condensing or non-condensing. For convenience the whole of the exhaust steam may be carried through the heating chamber, the surplus or uncondensed steam being passed on to the atmosphere or condenser, as the case may be.

The apparatus may be made with parts readily removeable and easily replaced for collecting deposits from impure water. The vent for steam may be closed, if desired. Air vessels may be applied where needed for equalizing the flow of water. The water may enter through the open end of the heating passage or through perforations; and the heating chamber may be formed with one or more contractions or strictures, so as to induce more intimate mixture of the water and steam, or with one or more bends or undulations.

The heating chamber or passage should be of sufficient length to effect the thorough heating of the water, but it may be supplemented where needed by one or more diaphragms placed within or beyond the passage, so as partly to baffle or divert the discharging currents of water and steam, and further to intermix them.

When the steam is delivered intermittently at considerable intervals into the heating chamber, as in the exhaustion of steam from an ordinary steam engine, the supply of the water to be heated may likewise be delivered intermittently, in order that cold water may not pass unheated through the heating chamber in the intervals of the discharges of steam. The intermittent supply of the water may be effected in a self-acting manner by the exhausting operation of the steam inducing a partial vacuum and a flow of water into the heating chamber through the water entrances, against which flap or other simple acting valves

may be placed, so as to open inwards when exhaustion is effected; or it may be effected by means of stop-cocks, or valves, or intermittent pumps, actuated by the engine. By means of valves, also placed at any convenient part of the delivery pipe or chamber, the supply-water may be sustained at the level to which it is elevated by the inducing action of the steam. The whole of the steam from donkey pumps used in feeding steam-boilers may be condensed in this manner. The apparatus may be protected by a jacketing of steam from the exhaust or otherwise, or by a coating of felt or other material, to increase its efficiency by the addition of heating surface, and to prevent loss of heat.

The annexed illustrations exhibit various forms of the apparatus. In the Figures generally, *A* is the heating chamber; *B* is the steam pipe, from which the steam for heating the feed-water is discharged; *C* is the pipe, conduit, or vessel which contains and conveys the water to be heated. The water enters the heating chamber through perforations or slots *a, a*, so as to meet and mix with the entering steam, and the heated water is discharged into the cistern *D*, from which it is drawn off by the pipe *E* to be pumped into the boiler. Any residual steam in the cistern *D* may escape through the waste pipe *F*.

In Fig. 1 the heating chamber is enclosed in the water conduit, and is surrounded by the water. The tight air space at the upper end of the conduit acts as an air vessel. The steam nozzle is fitted air-tight into the heating chamber, in order to prevent the suction of cold air into the chamber, and the loss of heat thereby, and to sustain the exhaustive action of the steam. In Fig. 2 the heating chamber and water conduit are placed side by side, and united at the upper parts where the steam is admitted. In Fig. 3 the heating pipe and water pipe are enclosed within a chamber which contains the heated water. The cold water is discharged into an upper chamber, whence it proceeds to the heating pipe. In Fig. 4 there are three heating pipes and three steam nozzles, one to each pipe, enclosed within the water conduit. In Fig. 5 there are several steam nozzles placed in a circle, playing into an annular

heating chamber placed within the water chamber. The cold water enters the annular chamber from within and from without. In Fig. 6 the steam is admitted in several jets into the heating chamber, which in this case is plain. In Fig. 7 the cold water is admitted in one or more thin sheets into the heating chamber. Fig. 8 illustrates the adaptation of a ball-cock to the cold water supply-pipe, to maintain the water at a constant level in the cold-water cistern, and is useful when the water is supplied from above the level of the heating apparatus. Fig. 9 shows an application of the invention to a locomotive, in which the heating chamber is placed horizontally over the barrel of the boiler. One pump may be employed to supply the cold water, and the other pump to supply the heated water to the boiler. When the feed pump is not in action, the heated water flows freely back into the tank or tender. Figs. 10, 11, 12, 13, show various other forms of the apparatus. In Fig. 10 a core is introduced within the heating chamber under the steam nozzle to diverge the steam, and so to promote the mixture of the steam with the water. In Fig. 11 the steam is discharged from an annular orifice near to the circumference of the heating chamber. In Fig. 12, also, the steam is discharged from an annular orifice, and the water is introduced against the steam from within and from without the annular orifice.

In the illustrations it has not been thought necessary to show in detail any of the obvious and well-known modes of conveying steam to the heater, or of inserting linings or vessels for the collection and easy removal of deposits from impure water. It is obvious also, without further illustration, that by a suitable disposition of cocks or valves the apparatus may be turned off at any time and the engine maintained in working order.

STEAM NAVIGATION ON THE RIVER AMAZON.

MR. LAIRD, of Birkenhead, has just completed a vessel for a company formed under the auspices of the Baron de Mauá, of Rio Janeiro, for the navigation of the river Amazon. This vessel is named the *Mauá*, she is 255ft. long and 25ft. beam. Her tonnage, old measure, is 681, and she is intended to combine great carrying capacity with speed. She is arranged something on the plan of the American river boats, the decks being carried out to the extreme width of the paddle-boxes, and the whole of the accommodation for first and second-class passengers is in large deck houses, leaving the holds entirely free for cargo and coals. Her engines, also constructed by Mr. Laird, are of 180-horse power nominal, but worked on the trial to between 950 and 1,000 indicated horse-power. The paddle-wheels are on the feathering plan, and the boilers are fitted with superheating apparatus, and other modern improvements. In order to test this vessel's capabilities for speed and seagoing qualities, she was despatched from Liverpool to Beaumaris on Monday last, and made the passage from the Rock Light (a distance of 48 statute miles) in three hours, giving an average speed of 16 miles per hour. She returned from Beaumaris to Liverpool on Wednesday in 2h. 50min., being an average speed of 17 miles per hour. The *Mauá* was partially loaded, and had on board two large iron barges shipped in pieces, to be riveted together on arrival at Para, besides a considerable quantity of coal. The distance between Liverpool and Beaumaris has never been accomplished in so short a time before. The vessel and machinery have been constructed, and the above trial of speed made, under the superintendence of Commodore Hoffsmith, a distinguished officer of the Brazilian navy, who was sent over by the company for that purpose, and also to superintend another vessel now being constructed by Mr. Laird for the same owners.—*Times*.

A number of additional hands have been set on recently at Woolwich Dockyard and Steam Factory Department, and riggers are still required, who will receive a considerable advance of wages.

THE STRENGTH OF WROUGHT IRON AND STEEL.

THE following condensed abstract of a first set of experiments, made by Messrs. Robert Napier and Sons, on the strength of wrought-iron and steel, was communicated to the British Association at the Aberdeen meeting by Professor W. J. Macquorn Rankine, C.B., LL.D., &c.:—The experiments to which this abstract relates form the first set of a long series now in progress by Messrs. Robert Napier and Sons, the details being conducted by their assistant, Mr. Kirkaldy. The whole results are now in the course of being printed *in extenso*, for publication in the "Transactions of the Institution of Engineers in Scotland;" but some time must elapse before they can appear, owing to the great volume of the tables, and the number of particulars which they give.

The present abstract is all that it has been found practicable to prepare in time for the meeting of the British Association, and, notwithstanding its brevity and extreme condensation, it is believed that the results which it shows will be found of interest and importance. It gives the tenacity, and the ultimate extension, when on the point of being torn asunder, of the *strongest* and the *weakest* kinds of iron and steel from each of the districts mentioned. Each result is the mean of four experiments at least, and sometimes of many more.

The detailed tables, now being printed, will show many more particulars, and especially the contraction of the bars in transverse area along their length generally, owing to "drawing out," and the still greater contraction at the point of fracture. The experiments now complete were all made with loads applied gradually. Experiments on the effect of suddenly applied loads are in progress.

TABLE A.—IRON BARS.

	Tenacity in lbs. per sq. inch.	Ultimate extension in decimals of length.
Yorkshire: strongest	62886	0.258
" weakest	61975	0.205
" (forged)	65322	0.202
Staffordshire: strongest	62231	0.222
" weakest	56715	0.225
West of Scotland: strongest	61795	0.173
" weakest	56855	0.191
Sweden: strongest	48232	0.264
" weakest	47855	0.278
Russia: strongest	58405	0.153
" weakest	49581	0.133

TABLE B.—IRON PLATES.

Yorkshire: strongest lengthwise ..	55005	0.111
" weakest lengthwise	52000	0.131
" strongest crosswise	60515	0.093
" weakest crosswise	46221	0.076

NOTE.—The strongest lengthwise is the weakest crosswise, and vice versa.

TABLE C.—STEEL BARS.

Steel for tools, rivets, &c.: strongest ..	132900	0.054
" weakest	101151	0.108
Steel for other purposes: strongest ..	92015	0.153
" weakest	71486	

TABLE D.—STEEL PLATES.

Strongest lengthwise	94250	0.0371
Weakest lengthwise	95591	0.1086
Strongest crosswise	96308	0.0354
Weakest crosswise	69016	0.1901

NOTE.—The strongest and weakest lengthwise are also respectively the strongest and weakest crosswise.

COINING BY CONTRACT.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In the article "Coining by Contract" in your last week's impression, you assume that we have obtained a promise of contract for the proposed new bronze coinage.

We beg to state that we have received no such promise, either directly or indirectly, and that we are not in any way responsible for the paragraph in the *Manchester Guardian*, from which the inference has been drawn.

Your obedient servants,

RALPH HEATON AND SONS.

Birmingham, November 7th, 1859.

Proceedings of Societies.

INSTITUTION OF MECHANICAL ENGINEERS.

THE general meeting of the members of this Institution was held on Wednesday, the 2nd instant, at the house of the Institution, Newhall Street, Birmingham, Henry Maudslay, Esq., Vice-President, in the chair. The Secretary (Mr. W. P. Marshall) having read the minutes of the previous meeting, held in Leeds, the chairman alluded to the irreparable loss that had been sustained by the profession and the world at large in the recent lamented death of Mr. Robert Stephenson; and desired to express, on behalf of the meeting, their high appreciation of his great mechanical genius and their warm admiration of his many noble qualities. Mr. Stephenson had taken a strong interest in the development of the Institution in its earlier years, having succeeded in the presidency his father, the late Mr. George Stephenson, their first president; and both had largely aided in promoting its welfare by their counsel and assistance. A considerable number of new members were elected; and the president, vice-presidents, and members of council were nominated for the next annual election.

The first paper read was a "DESCRIPTION OF OATES'S BRICK-MAKING MACHINE," by MA. JOHN E. CLIFT, of Birmingham. In this machine, which is the invention of Mr. J. P. Oates, of Erdington, near Birmingham, the bricks are made direct from the clay, without previous preparation beyond passing through the ordinary crushing rollers when containing a mixture of stones. The machine consists of a revolving vertical screw with a large flat blade, widened conically at the upper part, and working freely within a cylinder, at the bottom of which is the mould block, sliding horizontally, containing two moulds in which the bricks are formed. The upper part of the cylinder is expanded to form a hopper, into which the clay is supplied, and is then drawn down into the cylinder by the revolution of the screw and pressed into the mould below. The mould thus filled is then withdrawn horizontally, and the other empty mould brought under the screw to be filled with clay; and the first brick is discharged from the mould by a vertical piston pushing it through the open bottom of the mould on to an endless band, by which it is conveyed to the front of the machine ready to be removed direct to the kiln for burning. The clay is supplied continuously by the action of the screw; and, at the instant when the bottom of the clay cylinder is closed by the change of moulds, an outlet for the clay is provided by means of a horizontal escape pipe, opening from the bottom of the clay cylinder, and acting as a safety valve to prevent any excess of pressure in the machine or any risk of overstraining. The outer end of this escape pipe is open, and the friction of the clay against its sides determines the limit of pressure in the machine: the clay is pushed forward in the pipe $\frac{1}{2}$ or $\frac{3}{4}$ an inch each time the brick moulds are changed. The bricks are completed at a regular rate of 12,000 per day in ordinary work, or an average of twenty good bricks per minute; and the machine is capable of making as many as thirty bricks per minute. Several of these machines are at work in the neighbourhood of Birmingham and elsewhere, some of which have been working regularly for three years. The crushing strength of the bricks has been found to double that of hand-made bricks of the same district; and their transverse strength is also considerably greater than that of hand-made bricks. No difficulty is experienced from the bricks not having been dried before stacking in the kiln for burning, as they are sufficiently dry on leaving the machine; so that the process of drying required for hand-made bricks previous to burning is dispensed with. A number of samples of the ordinary bricks made by the machine were exhibited, and specimens made from different qualities of clay in different parts of the country; also a working model of the pressing screw and escape pipe of the machine, showing the

action of the vertical screw in forcing the clay out laterally through the horizontal pipe.

The next paper was a "DESCRIPTION OF A NEW CONSTRUCTION OF HIGH-PRESSURE STEAM BOILER," by MR. J. FREDERICK SPENCER, of London. This boiler, the invention of Mr. M. Benson, of Cincinnati, U.S., is of tubular construction, and is designed for the purpose of generating steam of high-pressure without risk of accident to any portion of the boiler, by producing an artificial circulation of the water in the boiler, by mechanical means; it is also intended to combine great lightness and compactness of construction. The boiler consists of a series of horizontal tubes of small diameter, arranged in parallel rows over the furnace, and communicating at top and bottom with a receiver placed outside. The mechanical circulation of the water is produced by means of a pump worked by the engine, which draws the water from the receiver and drives it through a series of tubes, from the top of which it passes back into the receiver in the form of mixed water and steam. The boiler is divided into separate sections, each communicating independently at top and bottom with the receiver, and capable of being readily removed for repairs; the series of tubes in each section are connected alternately at the ends by semicircular bends, so that each section presents a continuous passage for the water, which is driven through the tubes by the circulating pump at the rate of about ten times the quantity evaporated. The power required to work the pump is very small, having merely to overcome the friction of the water in passing through the tubes; and in first getting up steam the pump is worked by hand for a short time, until there is steam enough to work it. The quantity of water contained in the boiler is much smaller than in ordinary boilers, enabling the steam to be raised in a much shorter time; while the mechanical circulation ensures all the water being uniformly heated throughout, and prevents any part of the tubes being burnt in consequence of deficiency of water. The risk of explosion of any part of the boiler is much diminished, the tubes being of great strength in consequence of their small diameter, while the receiver is not exposed to the action of the fire. Several of these boilers have been at work for some years in America, where they are in use principally for steam fire engines; for this purpose their rapidity in raising steam is of great value, and steam of 60 lbs. per square inch pressure has been raised in as short a time as six minutes from cold water. The tubes are found to be very durable, and do not become choked with deposit, though the boilers have been worked for many months with water containing a large amount of deposit; the deposit is carried over continuously into the receiver, while the tubes are kept clear by the regular flow of water produced through them by the mechanical circulation.

The meeting then terminated.

ASSOCIATION OF FOREMEN ENGINEERS.

On Saturday the 6th inst, the Association of Foremen Engineers held their ordinary monthly meeting at St. Swin's Hall, City, Mr. Newton, President, occupying the chair, and Mr. John Jones, Secretary, the vice-chair. Soon after 8 p.m. the business of the evening was opened by the reading of the minutes of the previous meeting, the formal electing of Mr. Ebbery as an ordinary, Mr. Fowler as an honorary member, and the nomination of Mr. Hepburn, of the Small Arms Factory, Enfield, as a prospective ordinary member. There was a goodly assemblage of foremen present, and the President next called upon Mr. C. F. HAYES to continue his series of papers on THE MANUFACTURE OF SMALL ARMS. That gentleman at once responded to the invitation, and proceeded to describe in his usual terse and explicit manner, the various parts of the rifle musket which are known as its "furniture." The trigger was first spoken of. This was of wrought iron, roughly forged in the first instance, then struck, at a proper heat, into a pair of dies, then put through a succession of milling, or drilling operations and

lastly polished and case hardened. The trigger plate was of brass compound—as is all the brass portions of the furniture of the rifle—of a mixture of sixteen parts copper, ten of zinc, and one of lead. It was passed through several milling, drilling, and tapping processes, and edged by a machine which, originally of American origin, had been much improved by Mr. Hague. Finally it was polished on buff wheels and made ready for attachment. The guard plates, also of brass, had to pass through a number of machines prior to polishing, and these were described by Mr. Hayes. The butt plate, of brass, thanks to the ingenious arrangements made by Mr. Hague, who had been rewarded by the War Office for his pains, was finished off much more rapidly and perfectly than heretofore, the machines used being admirably adapted to their purposes. The ramrod, of steel, except the rammer end, which was of wrought iron, had to be clamp-milled, screwed, hardened and tempered, then ground, polished, tested, and gauged. The nose-cap, of brass, was now, owing to important improvements made by J. H. Burton, Esq., chief engineer at Enfield, finished with great rapidity and consequent economy. The rod-spring, of steel, was forged by hand into a die, then bent into a spoon shape, and afterwards milled, hardened, tempered, and polished. The rod-stop was punched out of a rod of iron, filed by hand, and thus finished. The side-cups were punched from sticks of cast-brass, then coned in dies, drilled, counter-sunk, milled to thickness, and polished. Next came the bands for fastening the barrel to the stock, and in the mode of treating these the chief engineer had recently devised considerable improvements, principally in the forging, and which involved the use of Nasmyth's steam drops, dies, &c. By these means great economy of labour and of money were effected. These bands were as neat when completed as the bracelets of a lady, and, as might be imagined, they underwent much careful manipulation. The guard and band swivels were of wrought-iron, put through numerous minute operations, and lastly "blued." The screws, nuts, and pins for the whole of the furniture, although not attracting much attention when in their places, were all prepared with such accuracy as to preclude the possibility of their turning loose in action, and were indeed most carefully fitted.

The back-sight was a most important piece of furniture. By its means the rifleman regulated the range of his rifle, and made sure of his mark whether it was at 100 or 1,000 yards distance! The "bed" of this contrivance, which rested on the barrel of the weapon and closely fitted it, was of wrought-iron, forged firstly by hand, and secondly struck between top and bottom dies under Colt's screw drop hammer.

About fourteen or fifteen distinct processes were wanting before the back-sight with its graduated gauge, springs, and fittings was ready for application to the breech of the rifle; and lately a prize had been awarded to Mr. Williams, of the Enfield factory, for certain improvements in some of these processes. The slide, the leaf, the spring, and the cap form parts of the back-sight, and each requires careful workmanship.

It is needless to say that the above is but an abstract of the valuable and comprehensive paper read at the meeting of Foremen Engineers on Saturday, and to the thorough comprehension of which Colonel Dixon, R.A., of Enfield, contributed largely by allowing specimens of each article of "furniture" alluded to be "laid on the table." The lock and stock of the rifle will form the concluding themes of Mr. Hayes' elaborate dissertation, and the manufacture of these will be explained at the ensuing December meeting.

Some beautiful LUNAR PHOTOGRAPHS and MAGNETIC DIAGRAMS, kindly forwarded from the Royal Observatory at Kew, were, at the conclusion of the above-named paper, handed round and explained by Mr. Beckleigh. These excited much interest among the numerous auditory—who were anxious, as a gentleman happily expressed it, to "learn of the invisible

through the medium of the visible." It was eleven o'clock before the pleasant proceedings of Saturday came to a close, and it was only regretted that employers—who, according to a contemporary, are afraid that "shop secrets" are divulged at their foremen's *réunions*—were not more numerously represented on the occasion in the handsome apartment in which this meeting was held.

Messrs. Keyte (of Woolwich), Brigga, Ballard, the President, and others took part in the friendly discussion which ended the meeting, and all departed with a high sense of gratification.

WATCHMAKERS' ASSOCIATION, COVENTRY.

ON Tuesday evening, Nov. 1, a lecture on horology was delivered by JAMES FERGUSON COLE, Esq., Vice-President of the British Horological Institute, London. Mr. Cole was accompanied by Messrs. Brooks and Sheppard, members of the Council of the Institute. The attendance was very large, and amongst those present were some of the principal watch manufacturers in the town.

The Lecturer said he had accepted the invitation to deliver a lecture, in the hope of being able to submit a few observations referring to the principle of timekeepers, but chiefly with regard to chronometers and pocket-watches, as portable machines dependent for time-keeping effect on the vibratory motion of a balance governed by the elastic resistance of a balance-spring; while clocks, as fixed machines, depended upon the oscillatory motion of a pendulum, governed by the principle of gravity. With reference to the "spring" or "weight," as the usual motive power applied to the machines alluded to, he explained that neither one nor the other of these was of itself a power, and hence the mainspring as belonging to the class of timekeepers now treated on might be considered as only a reservoir of the force exerted by the hands in the act of winding up the spring. Elasticity was not, therefore, a power, but, on the contrary, a constant principle of resistance, tending only to obstruct motion, and to remain, like the inert matter of a weight, constantly in a condition of rest; but when a spring was wound into tension, its tensile force would be given out in the way of re-action, and whether it be a mainspring, a balance-spring, or the tremulation of a bell, all were alike obedient to the great ruling principle of nature, in which the deepest philosophical scrutiny had never detected the smallest error. Having described the construction of the chronometer or pocket-watch, he proceeded to observe that escapements were of various constructions, but those most generally adopted in the manufacture of watches during the last half century were the horizontal, the duplex, the chronometer detached, and the detached lever escapement. There was also another class of escapement, known as the Remontoire, but after many experiments, he found that the remontoire spring must always be fully under control of the mainspring at its lowest tension as an arbitrary condition, and that when the mainspring was fully wound to its highest tension the pressure from the motive force to the scape-wheel locking was so great against the delicate remontoire spring which had to discharge it, that it required too nice an adjustment of the force and resistance to be relied on. The same disadvantage attended the remontoire in regard to fusee movements, where the maintaining spring was inferior to the mainspring; and although the same objection to the remontoire did not so strongly apply where the motive power was uniform by a weight as in clocks, in this application of the principle, under the most favourable circumstances it was still open to objection, as the smaller irregularities of power through the train of wheel-work, together with the impediment of thickened oil, and the effect of various temperature on the spring, rendered this delicate winding action so very doubtful that he had long since given up the use of the remontoire escapement. The principle involved in all escapement mechanism in watches

was in its general aspect of simply a mechanical character, and, viewed in this light, must appear only as a means of transmitting impulse power to the pallet plains. Such, however, was not strictly the case, as any undue resistance arising from defective application, or from a want of correctness in the formation of the locking angles, &c., on whatever principle of escapement, was well known to affect both the mechanical result in motion produced, and also the isochronous result on time. With regard to the lever escapement now generally adopted for ordinary pocket watches, the rudimentary principle was strictly that of Graham's pendulum clock, although ascribed to Mudge as its inventor, and it must be regarded in its present shape as a valuable improvement for its greater simplicity and ease of execution, and as effecting the important object of detachment of the balance. In reviewing as he had done the various modes of construction of chronometers, pocket-watches, and other time-keepers, it was not his intention to offer any rigid rule or process for the attainment of an end which practical watchmakers arrived at by their own peculiar modes established by custom and experience. What he proposed was a reduction of the proportions of the mechanical parts of the detached lever escapement to a rule, which, if correctly observed and adopted, must lessen or prevent the liability to failure in the ultimate mechanical and time-keeping results when made by workmen of less mature experience. The first consideration was, what should be the proper diameter and weight of the balance for the proposed watch movement; This, he need not say to the scientific watchmaker, was only to be ascertained in the first instance by mechanical trial and by the result in motion produced. That the weight should bear some preferable relation to the diameter could not be doubted, as either carried to an extreme must destroy the harmony of proportion. The lecturer here proceeded to detail at considerable length the mode by which he had attained the object alluded to, and with the aid of diagrams clearly showed to his audience the state of simplicity to which he had reduced his principle. In conclusion, the Lecturer urged upon all watch manufacturers the desirability of rendering the construction of chronometers, pocket-watches, and other timekeepers as little complicated as possible, remarking that all the varied and improved modes of action described by him had been found to work well, and it was owing to their being based upon the simplest form of the principle that he gave them the preference.

INSTITUTION OF CIVIL ENGINEERS.

TUESDAY, Nov. 8.—The first meeting of the present session took place in the evening of this day; previous to commencing the proceedings the president, Mr. J. Locke, M.P., offered a few observations as a tribute to the memory of Brunel and Stephenson—two of the Institution's "most honoured and distinguished members."

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

November 1st.—J. P. Joule, LL.D., F.R.S., Vice-president, in the chair. A paper was read by Mr. JAMES G. LYNDY, M. Inst. C.E., F.G.S., on **EXPERIMENTS ON THE STRENGTH OF CAST IRON GIRDERS.**

October 5th.—**MATHEMATICAL AND PHYSICAL SECTION.** The following gentlemen were elected officers of the section for the present year:—President, Robert Worthington, F.R.A.S., Vice-presidents, J. W. Long, F.R.A.S., & W. Binney, F.R.S., F.G.S., Treasurer, Joseph Baxendell, F.R.A.S., Secretary, Mr. Thos. Heelis.

October 13th, 1859.—Mr. Baxendell read a paper ON THE PHENOMENA OF GROUPS OF SOLAR SPOTS.

A paper was also read by Mr. Thomas Carrick, on the relation which appears to subsist between ORBIT DISTANCES AND ORBIT INCLINATIONS, when the latter are referred to the solar equator as a fundamental plane.

NOTICES.

The **MECHANICS' MAGAZINE** will be sent free by post to all subscribers of £1 ls. 8d. annually, payable in advance. Post Office Orders to be made payable to L. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5s. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 32 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

OUR APPEAL.

IN addition to the numerous sums announced in our last number, we have received the following:—J. S. R., £2 2s.; J. C., £2; C. S., 10s.; R. L. T., 10s.; C. P. C., 10s.; S. H. B., 5s.; An Inventor, (Glasgow) 2s. 6d. The total sums received up till to-day, Thursday, amount therefore to £22 5s. 6d. For this we are requested to express the heart-felt thanks and gratitude of the receiver. We need not, we are sure, multiply words on this subject. We will only say that the sum already equals our expectation, seeing that the claim upon our readers was a remote one, and supported by no recommendation save that of pure charity. Of course if more is sent we shall be happy to receive and forward it.

Our Weekly Gossip.

THE following suggestion from Mr. Chubb, of the well-known firm of St. Paul's Churchyard, London, should be attended to:—

GENTLEMEN.—The loss of the Royal Charter should direct the attention of shipbuilders, and others interested in the matter, to the improper method of constructing the bullion rooms on board ship. These receptacles are usually formed by lining some nook or corner with strong iron plates, bolted to and forming part of the ship, so that if the vessel gets on shore and breaks up, the bullion room necessarily goes to pieces with it, and the contents are dispersed. I would suggest that these safes should not be in any way connected with or fixed to the ship. In case of a wreck and the breaking up of the vessel on shore, the safe would go to the bottom, preserve its contents intact, and be readily recovered. As a safe four feet square will hold more than 2,000,000 sterling, very little space would be interfered with.

I am, Gentlemen, your obedient servant,
J. CHUBB.

St. Paul's Churchyard.

When the fleet was off the Eddystone lighthouse in the late gale, Admiral Elliott, with the true spirit of a true British admiral, decided at once to "wear the fleet together and stand off and face the gale," and while doing so a man fell overboard from the jibboom of the Trafalgar, which with the Emerald and Aboukir formed part of the "sternmost line;" but notwithstanding the violence of the gale and the heavy sea running at the time, one of the cutters with a full crew in it was instantly lowered by "Clifford's" lowering gear, (as now generally fitted by the Admiralty in the ships of the Royal Navy,) and the man providentially saved. The *Times* of yesterday contains an important letter on this subject from Mr. Clifford, in which he very pertinently says:—"Now, if a heavy man-of-war's cutter, with all its crew in it, could be thus instantly and safely lowered in one of the heaviest gales that ever broke upon our coast, we may at once infer how much more easily the same operation might be performed from a merchantman, where everything being on a less cumbersome scale necessarily entails less risk or liability to accident. But in how many of the ships, the harrowing recitals of the wrecks of which you have so repeatedly and so graphically chronicled of late, has anything of the kind been on board? Was the Royal Charter so provided, or do the owners of any of the hundreds of the huge passenger ships of her class that leave our shores ever give one moment's heed to such absolute necessities? Let any one who doubts what I say take the trouble to go through our docks and inspect a few ships all duly passed 'as ready for sea.' He will not be long in finding that, in spite of laws putting a fine of from '£5 to £50 on the master of every passenger ship not having a longboat and a lifeboat fitted so as to be most available for immediate service (18th and 10th of Victoria, cap. 119), or the Board of Trade Circular, No. 51, January, 1857, that 'surveyors are to refuse declarations in future in cases in which the lifeboat is not in such a position as to be ready for use in an emergency, or in which efficient means are

not provided for lowering it safely and expeditiously into the water;' I say, however incredible it may seem, yet he will not find one ship in a hundred that complies with these provisions, or any officer who, knowing them to be deficient, ever attempts to enforce such distinct and positive rules, the wanton disregard of which his superiors knowingly wink at."

A correspondent of the *Times* writes as follows:—There are three great difficulties attendant on the use of the "rocket" in the case of shipwreck or vessels in distress:—1. The uncertainty that necessarily attends its flight, especially in strong winds (times when it is most generally needed). 2. The impossibility virtually of its always being on the spot where required. 3. The impracticability of its rapid use on such parts of a coast as are rocky, marshy, &c. Query.—Would not all these difficulties be removed and many other advantages gained by the vessel itself carrying the rocket apparatus—a precaution quite feasible, at all events to large vessels? 1. The difference between the accuracy of its flight and that of the land rocket would be equivalent to the difference in the difficulty between hitting a centre of a circle from its circumference and the circumference from its circle. 2 and 3. Not only would it always be at hand and available, but it would be equally efficacious on the shores of a desert island as on the coasts of Kent; and, among many other advantages which suggest themselves, its fire light in the air (at night) would indicate to coastguards, &c., the place where the rope was landed. This seems as simple as well as important an expedient that I can hardly believe that there can be any novelty in the idea. As, however, I have never heard or read of this application of the rocket system, I beg to forward you the suggestion, should you think it worthy of a place in your columns.

It is stated that the entire establishment composing the Royal Gun Factories in Woolwich Arsenal is about to be remodelled, an immediate cessation of casting guns of every description having been decided on, in order to give place to the introduction of Sir William Armstrong's method on the most extended possible scale. Sir William Armstrong and Mr. Anderson, conducting the rifled ordnance department at Woolwich, were on Saturday summoned to a lengthened conference with the Secretary of State for War, on the subject of transferring the whole of the Royal gun factories to that department which, it is expected, will be put into effect by official announcement without delay. The casting metal on hand, as well as the unfinished brass guns, are ordered to be handed over to the Laboratory to be appropriated to other uses. One of the experimental cast-iron ordnance, termed a shunting gun, rifled on Sir William's principle, has been tested at Shoeburyness, as we stated a week or two since, and burst under trial. This, together with other experiments entered into, has borne out the impression made on the minds of the Ordnance authorities, that cast ordnance are not of sufficient strength to resist the force exerted with the rifle bore, and that wrought iron alone is applicable for that purpose. The casting furnaces recently erected will be employed in the manufacture of shells and other purposes; and the Artillery officers connected with the department will return to their military duties.

The *Times* of yesterday adds the following information on this subject:—"The first step in advance towards the long contemplated reorganisation of the important establishment composing the gun factories in Woolwich Arsenal was yesterday taken by handing over the direction of the department in due form from the military to the civil service, to be conducted in future under the auspices of Sir W. Armstrong, C.B., and the resident superintendence of Mr. John Anderson, late inspector of machinery. Great preparations are made for manufacturing rifled ordnance on Sir William's principle, calculated, according to present arrangements, to bring out, at the lowest computation, 1,000 guns a year, with the prospect of a considerable addition to that number, in case of actual demand. A number of cast-iron guns will be made in the factories and by the trade for experimental use, to be encased in a kind of net-work, termed a 'chemise,' composed of wrought-iron, which it is suggested will add to the endurance of the inner metal of which the gun is cast, and render it sufficiently strong for the purpose. The new department has received instructions to bring out as speedily as possible a batch of 40 6-pounder rifled guns to carry the elongated shot for field service in China, to be transported overland. It is stated that, as a necessary consequence of the whole of the gun factories being employed for the manufacture of Sir William's guns, the shot and shell foundries will be ultimately handed over to the same direction, and that the superintendence of the laboratory will merge into that of the gun factories, which will create a reduction of no insignificant importance in the general expenditure."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 875.

BOILERS AND THEIR FURNACES, &c., 832, 866.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 842, 862, 867.

SHIPS AND BOATS, including their fittings, 843, 844, 845, 854, 860.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 868, 869, 870.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 839, 859.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 830, 835, 838, 847, 847, 849, 850, 855, 856, 865, 876.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 833, 836.

LIGHTING, HEATING, AND VENTILATING, 828, 832.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 841, 851, 858.

METALS, including apparatus for their manufacture, 826, 846, 848.

CHEMISTRY AND PHOTOGRAPHY, *None*.

ELECTRICAL APPARATUS, 837, 863.

WARFARE, 840, 864, 874.

LETTER PRESS PRINTING &c., *None*.

MISCELLANEOUS, 827, 829, 831, 834, 833, 857, 861, 871, 872, 873, 875, 877.

826. A. BESSEMER. "Improvements in furnaces to be employed in the manufacture of iron and steel." Dated April 2, 1859.

This consists in constructing furnaces for the manufacture of iron and steel with a portion of the bed thereof raised above the level of the remaining part of the bed, and in so mounting such furnaces that, by suitable machinery, the beds shall rock or perform an up and down motion, thereby causing the metal to be roused about and turned over. *Patent abandoned.*

827. S. DESBOROUGH. "Improvements in making up needles, steel pens, and other small articles for sale." Dated April 2, 1859.

The inventor takes a piece of paper, tin, &c., of suitable form, and by means of dies or tools he forms or impresses on the surface of such material a number of grooves, channels, or corrugations according to the number of needles the package is intended to contain, and he afterwards folds over those parts which are not impressed, and secures them, leaving one end of such series of grooves open to introduce the needles, that end being afterwards covered by a loose flap folding over. He introduces into each case, when being made, a thin strip of magnetized iron or steel, which will attract needles and prevent them falling out of the grooves. *Patent abandoned.*

828. J. SKERTCHLY. "Improvements in apparatus for regulating the pressure of gas." Dated April 2, 1859.

This consists, 1, in the construction of oscillating valves for regulating the supply of gas to the burner. These valves work in mercury, and are so arranged as to release on one side of their centres a corresponding amount of mercury to the displacement of the other. 2. In constructing a vertical section valve by means of a small inverted cup, with slots or openings at its edges. 3. In reducing the pressure of gas by causing it to percolate through any suitable depth or thickness of granulated material. *Patent abandoned.*

829. W. MATHER. "An improved apparatus for catching and destroying flies and other insects." Dated April 2, 1859.

This consists of shallow dishes or vessels of tin, zinc, or other metal, with holes or projections in the sides to allow of their being suspended from the ceiling, in which any of the well-known poisonous or adhesive substances used for such purposes is placed. *Patent abandoned.*

830. A. PAGET. "Improvements in machinery or apparatus for the manufacture of looped fabrics, and in the manner of constructing the same." Dated April 2, 1859.

This consists, 1, in using a sinker to each needle, and actuating each sinker consecutively by an incline or otherwise; also in a method of supporting the

sinkers in a grooved bar or comb; also in a method of retaining each sinker in position by a spring; also in securing such springs to a bar by cement or solder. 2. In using a presser bar with garts or grooves for the sinkers to slide through. 3. In a method of producing a selvage on any needle in the frame by a thread-layer. 4. In a method of making a knocking-over-bar with the knocking-over pieces of steel plate, and of securing them in garts or grooves in a bar of brass. We cannot give space to the details of the invention. *Patent completed.*

831. M. SCOTT. "Improvements in diving apparatus." Dated April 2, 1859.

This mainly consists of the addition to the air pumps of an indicating cylinder containing a piston, the cylinder being open to the atmosphere at the top, and connected with the pump at the bottom by means of a pipe and stop-cock; the piston is loaded with weights which counterbalance the pressure of the air. *Patent abandoned.*

832. M. COUPLAND. "Improvements in furnaces." Dated April 2, 1859.

In furnaces wherein a part of the foil bars are made to rise, as the fuel is consumed, in place of the hand mechanism for raising or lowering such part or parts of the foil bars, the patentee applies hydraulic mechanism, or the pressure of steam. The moveable bars are actuated by levers which receive motion from the piston of a hydraulic cylinder. *Patent completed.*

833. T. RICHARDSON and G. W. JAFFREY. "Improvements in the arrangement and construction of harbours of refuge, breakwaters, sea walls, or barriers, and other like structures." Dated April 2, 1859.

This mainly consists of a line or series of tapered towers, cylindrical in transverse section, made of cast or wrought-iron, having a clear space between each equal to its diameter. The spaces are to be filled in with balks of timber, iron pipes, or tubes, so as to form a species of vertical lattice, or screen, to break the oscillation of the waves, but at the same time allowing the tides to flow freely through them. *Patent completed.*

834. T. WILLIAMS and J. H. FULLER. "Improvements in screw-stocks and dies." Dated April 2, 1859.

This consists in the adoption of two square dies, with a cutting surface on each edge, and a wedge at the back thereof, pressed down, drawn up, or propelled by certain arrangements. *Patent completed.*

835. F. POTTS and R. BROUGH. "Certain improvements in the manufacture of calico printing rollers or cylinders, also in the machinery and apparatus for performing certain parts of the same, and which said apparatus are also applicable, separately or conjointly, to the manufacture of parallel and other metallic tubes, and the rolling of the metal for the same, or other purposes." Dated April 4, 1859.

This invention comprises a variety of detail (as may be judged from the above lengthy title) which we cannot here quote at sufficient length for an intelligible abstract. *Patent abandoned.*

836. J. ECCLES. "Improvements in machinery for making bricks, tiles, and other articles formed of plastic materials." Dated April 4, 1859.

The object here is to prevent breakage or stoppage of the apparatus when by accident an obstruction gets into the pusher chamber by providing a plate so contrived as to slide or give way, and in combining rollers with machinery that shall crush and deliver the clay to the mill, and moreover, force the material through the pug-mill to be expressed through the moulding orifices. *Patent completed.*

837. C. F. KIRKMAN. "Protecting telegraph wires, and in using them for subterranean and submarine purposes." Dated April 4, 1859.

This relates to a mode of constructing and applying telegraph wires, and consists in placing the wires covered with gutta-percha within a network, plaiting, or braiding of cocoa-nut fabric. *Patent abandoned.*

838. C. F. KIRKMAN. "Improvements in the manufacture of cocoa-nut fibre yarn and matting." Dated April 4, 1859.

This consists in spinning cocoa-nut fibre into yarn by means of well-known spinning machinery, and in afterwards manufacturing such fibre into matting by means of machinery. *Patent abandoned.*

839. W. BROWN and C. N. MAY. "Improvements in hay-making machines." Dated April 4, 1859.

The inventor mounts the rakes or prongs for tossing the grass or hay on the same axis as the carrying wheels of the machine. On the frame in connection with the shafts they fix a ring with internal teeth concentric with, and in the plane of, a small pinion on the barrel or centre of the rake heads or prongs; they gear this pinion with the ring of teeth by means of three or other number of intermediate or idler

wheels, which are mounted on studs fixed to a plate carried round by the carrying wheels, which thus communicates a quick motion to the rakes. *Patent abandoned.*

840. J. H. BURTON. "Improvements in the manufacture of barrels for small fire-arms." Dated April 4, 1859.

Here the patentee takes a short solid cylindrical bar of steel which he slightly anneals. Through the centre of its entire length a hole of sufficient size to allow for the proper contraction when the cylinder is elongated is drilled, and the piece heated to the degree required in rolling steel. It is next subjected to the action of corresponding taper grooves on the peripheries of a pair of rollers. The cylinder is presented to those rollers upon fixed mandrils, and by them the size of the hole reduced in the elongation is determined. The barrel is then bored, turned, and finished in the usual way. *Patent completed.*

841. W. E. NEWTON. "An improvement in ladies' hooped skirts." (A communication.) Dated April 4, 1859.

This consists in constructing one or more of the hoops or springs of a skirt so as to preserve as far as necessary its inflexibility in an upward and downward direction in all parts except at a point or part on such side, where they are made flexible, in order that they may bend and allow the front portion to hang down over the front of the seat when the wearer is sitting down. *Patent abandoned.*

842. W. E. NEWTON. "An improved construction of retarding apparatus or break for railway carriages." (A communication.) Dated April 4, 1859.

The retarding apparatus which operates on the wheels is actuated by means of suitable gearing, connected with one of the axles of the running wheels, and this gearing is brought into action by means of a clutch box under the control of the guard, and is put in or out of gear by a screw shaft and lever. *Patent abandoned.*

843. C. RUSSELL. "An improvement in the working of marine engines." Dated April 4, 1859.

The patentee claims applying the vibrating motion of a pendulum (derived from the pitching of a steam vessel) for cutting off the steam during the descending pitch, through the intervention of a tappet shaft connected with the cut-off valve, which will ensure a sudden cut off. And in conjunction with this combination he claims the use of a race which will allow of the pendulum vibrating to a given extent, without operating upon the cut-off valve, and will ensure the efficient action of the pendulum when the pitching of the vessel exceeds the given limit. *Patent completed.*

844. M. A. CROOKER. "Improvements in paddle-wheels for steamers." Dated April 4, 1859.

This consists in graduating either the distance from the centre at which floats or buckets of equal size are set upon the wheel, or of proportioning the size, and of course the resistance of each individual float or bucket to the amount of effective power impressed upon the wheel at the time the float or bucket is passing through the water. *Patent completed.*

845. D. B. WHITE. "Improvements in arranging ships' and other pumps." Dated April 4, 1859.

According to this invention, when it is desired to raise water or other fluids from a lower to a higher level, over an intervening obstacle of greater elevation than the higher level of the water or other fluid, the patentee prefers to employ an ordinary lift pump which has combined with it a syphon-formed outlet pipe, which is carried up from the upper or other suitable part of the barrel of the pump over the obstacle above which the water or other fluid has to pass, and down again so as to dip below the water or other fluid at the higher level. *Patent completed.*

846. E. MORRISWOOD. "Improvements in coating metals." Dated April 4, 1859.

The patentee claims the sheeting of iron or copper by causing them to pass a certain number of inches below the surface of the coating metal. Also, the use of a box or arrangement for dividing the surface of the coating metal so as to have one kind of flux in one side of the sheets, &c., to be coated, and another or no flux at all on the other side. It also claims other features more or less connected with the above. *Patent completed.*

847. D. SOWDEN. "Improvements in Jacquard machines employed for weaving figured goods or fabrics." Dated April 4, 1859.

This consists in imparting motion to the bottom bar and groove of jacquard machines by means of two rods or slides, and one lever and one treading rod, which simplifies the working and gains increased thereof. *Patent abandoned.*

848. A. SHANKS. "Certain improvements in machinery for forging and stamping metals." Dated April 5, 1859.

The patentee claims, 1, the constructing of steam-hammers for forging machines operated by a rotary movement to work the valve or valves in lieu of cams or levers. 2. The use of two extra valves, to regulate independently the pressure of steam on either side of the hammer piston. 3. The forming of the piston rod part of the hammer into an elliptical shape, to prevent its turning round in the cylinder; also, the placing of an elastic buffer inside the cylinder for the piston to strike against. *Patent completed.*

849. G. HASLITINE. "Improvements in sewing machines." Dated April 5, 1859.

This consists in making a fast or knot-stitch, in addition to the ordinary shuttle stitch, by a simple construction and peculiar arrangement and combination of parts. The invention is not described apart from the drawings. *Patent completed.*

850. E. FAIRBURN. "Improvements in machinery for carding wool and other fibrous substances." Dated April 5, 1859.

This relates to a former patent, dated March 11, 1852, and consists in placing plates of thin metal betwixt the swift or carding cylinder and the doffer, such plates being fitted and fixed in position with one edge in close proximity to the surface of the swift, the other edge entering into narrow grooves formed or cut into the surface of the doffer at suitable distances, so that the cards on the doffer are thus formed into rings, which being separated by the plates at the point of contact with the swift of the wool, &c., is effectually divided into strips as it is transferred from the swift to the doffer, from which it is stripped and passes over grooved rollers to the rubbers. *Patent completed.*

851. L. BRIERLEY and H. GREENING. "A new or improved method of ornamenting metallic bedsteads and other articles of metallic furniture." Dated April 5, 1859.

The patentees claim ornamenting such articles by applying thereto designs upon paper, the said designs being either drawn, engraved, lithographed, printed, or otherwise produced, and either plain, coloured, gilt, or bronzed and applied to the article by a mixture of glue and paste, and afterwards varnished, stoved, and polished. *Patent completed.*

852. F. C. BAKWELL. "Improvements in open fire-places." (A communication.) Dated April 5, 1859.

The patentee claims the use of a recess or fire-chamber placed at the back of the fire-basket of the grate, in combination with a covering, either arched or flat, placed over the recess and fire basket, extending below the throat of the chimney for better consuming the smoke and gas emitted from the fuel. *Patent completed.*

853. G. F. CHANTRELL and E. DUTCH. "Improvements in the apparatus for regulating the quantity of water to be used for the flushing of water-closets and other purposes." Dated April 5, 1859.

This consists in the use of a water supply cistern having a double bottom forming a measuring chamber for containing the quantity of water required at each operation of the apparatus. Within the measuring chamber is placed a double-acting valve, which upon being elevated or depressed cuts off the supply opening between the cistern and the measuring chamber, and opens the discharge orifice formed in the bottom of the measuring box, and upon the action being reversed the supply valve is opened, and the discharge orifice closed. This double valve is acted upon by a system of levers, which levers receive their motion by a person entering the closet or otherwise. *Patent completed.*

854. B. BROWNE. "Improvements in propelling ships or other vessels through water." (A communication.) Dated April 5, 1859.

This relates to screw propellers, and consists principally in placing them very much before the stern-post of the ship, and well under the bilge thereof, so that the power will be greater, and acting more directly upon that part of the vessel will assist in giving her more speed and less vibration. It is proposed to employ double screws, or two screws or segments on shafts at each side of the stern-post, the said shafts being worked by any motive power. *Patent abandoned.*

855. J. HETHERINGTON, T. WEBB, and J. CRAIG. "Improvements in machinery or apparatus for spinning and doubling cotton, and other fibrous materials." Dated April 6, 1859.

The patentee claims, 1, driving the spindles by conical friction surfaces. 2. The use of apparatus for causing the cords to lap around, and to retire from the drag pulleys. 3. The use of slits formed in the flyers or tops of spindles, in conjunction with top bearings, also with slits; also the use of spiral top ends to flyers or spindles. 4. The use of two or more loose and fast wharves on one spindle. *Patent completed.*

856. T. SCOTT. "Improvements in preparing,

treating, or manufacturing fibrous materials, and in apparatus employed therein." Dated April 6, 1859.

This relates principally to the treatment of "China grass," or "rhea fibre." The material is primarily deposited in a chamber containing a cold or heated alkaline solution, composed of alkali and soap, or oleaginous matter and common soda, or soda and potash. After treatment in this solution the fibrous material is removed, and it is then laid in a heap for the gummy matter to become separated from the actual fibre. The fibre is then beetled, washed, and finished for hackling in the ordinary way. There are modifications included. *Patent abandoned.*

857. N. LIBOTTE. "An improved safety apparatus to be applied to cages in the drawing of coals." Dated April 6, 1859.

This consists of a safety apparatus in which claws, grips, or jaws are mounted upon shafts which are capable of being turned to the required extent by means of vertical or horizontal springs on such springs being released by the breaking of the rope or chain by which the chair is suspended. The springs being thereby set free to act upon the shafts and their jaws or grips, the latter are caused to grip or catch into the pit or shaft guides with a firm hold. *Patent completed.*

858. F. M. CRICHTON. "Improvements in clocks or time-keepers." Dated April 5, 1859.

This consists in a new arrangement of what is usually termed a "going barrel," or toothed spring box, applying the power of one only to work both trains. *Patent completed.*

859. T. P. LUFF. "Improvements in cheese-vats." Dated April 6, 1859.

This consists in making those vessels in which cheeses are pressed of metal instead of wood. The inventor makes them of the usual form, with loose shifting bottoms, and with discs or followers to be laid on the top of the cheese, and more or less perforated as required. *Patent abandoned.*

860. J. ADAMS. "An improved tubular chain cable guide for vessel's bulwarks." Dated April 6, 1859.

This consists in an improved manufacture of cable guide as made with its body or pipe curved in longitudinal section, the external surface of the flange being made in continuation of the curve of the body, and so that the chain whether running out or being drawn in shall pass over and on a curved surface, such as will prevent any link from being stopped so as to be broken. Such curve of the flange and the inner surface of the pipe will also operate to diminish the danger of breakage of a chain cable while the vessel held by it may be riding at anchor in stormy weather or while pitching on the waves. *Patent completed.*

861. J. A. H. BALLANDE. "An improvement in the preparation of writing-paper, and ink to be used thereon." Dated April 6, 1859.

This consists in introducing into paper oxides or metallic salts, the proportions of which may vary according to the intensity of effect to be produced. The agent preferred is proto-chloride of mercury, but any salt of iron, of copper, or any other metallic salt will answer. *Patent abandoned.*

862. W. OWEN. "Improvements in the manufacture of railway wheels and tyres, and in the apparatus employed therein." (Partly a communication.) Dated April 6, 1859.

This relates, 1, to a method of combining the felloes and the tyres, or any other parts of railway wheels, and consists in forming a dovetailed or other like hole groove or recess in the tyre or other of the two parts to be combined, and in forcing into this hole groove or recess the heated end of a rivet or bolt, or the heated edge or end of a bar or plate, so that the metal shall be expanded in the said hole, groove, or recess, and thereby be caused to hold the parts firmly together. It relates, 2, to improved methods of, and apparatus for, forming and combining the several parts of railway wheels and their tyres. According to one method the patentee forms the felloes of the wheels with parts of two different diameters, or with alternate portions of the periphery of two different radii, and also by preference of a dovetailed form. The tyre of the wheel is formed with a corresponding dovetailed groove all round its interior, and with parts of its internal edge cut away so as to allow of the large alternate portions of the felloe being dropped into the recesses in the tyre, and then to be turned round in the tyre so as to lock themselves in the dovetailed groove. This brings the alternate small portions of the felloe opposite to the recessed portions of the tyre, and the vacant spaces thus left are filled up by plates of a suitable shape which may be rivetted to the felloe. Again, in order to facilitate and improve the manufacture of railway wheels by means of dies under a powerful hammer, the patentee forms the parts

which are to form a nave (by stamping in dies or otherwise) with aloping or inclined projections to receive corresponding ends of spokes, and in some cases he also recesses the nave, and forms the spokes with projections to fit in the recesses. The object is to provide either for heating all the parts at once, or for heating any two or more of them separately, and then bringing them together in a heated state to be acted upon by the hammer dies. There are various other features comprised in this invention, but to which we cannot specially allude for want of space. *Patent completed.*

863. J. ROGERS and E. J. TWEED. "Improvements in coating conducting wires used for electric telegraphic purposes." Dated April 6, 1859.

Here the conducting wire or wires are first coated with gutta-percha or india-rubber, and longitudinal bands of braided or plaited hemp are applied so as to surround the insulated wire or wires, and these longitudinal bands may be bound round with yarn or not to retain them, and then a coating of wires which have been previously bound with hemp or flax are braided or plaited over the outer surfaces of the parts previously combined. *Patent completed.*

864. J. SCOFFERN. "Improvements in lubricating projectiles and cartridges." Dated April 6, 1859.

This consists in employing for this purpose a composition prepared by mixing together paraffine and naphthalene. *Patent completed.*

865. D. MOSELEY. "Improvements in the manufacture of cards for carding cotton and other fibrous materials." Dated April 7, 1859.

This consists in manufacturing the backs of cards of cloth composed of woollen web and cotton or linen warp covered with a sheet of india rubber in its native state cut from a cylindrical block. The sheet of native india-rubber is attached to the fabric by cement. *Patent completed.*

866. A. CHAPLIN. "Improvements in steam-boilers." Dated April 7, 1859.

This consists, 1, in constructing boilers with tubes crossing the water surface line, such tubes being contracted below such line, and re-expanded. 2. In combining in boilers tubes of different effective calibres, so as to obtain more equal currents throughout the series. 3. In constructing vertical tubular boilers with increasing horizontal area internally, at and immediately above the water surface line. The invention is not fully described apart from the drawings. *Patent completed.*

867. R. POSTLETHWAITE. "An improvement in harness pads for horses." Dated April 7, 1859.

This consists in fitting such pads with hinges made of one piece with, or firmly fixed to, the metal frame on which the said pads are made in order to render them flexible, and thus allow of their expansion or contraction when required for a different sized animal. *Patent completed.*

868. R. WARDELL and H. KEARSLY. "Improvements in reaping machines." Dated April 7, 1859.

This relates to a former patent, dated April 1, 1857, and comprises several improvements which are not described apart from the drawings. *Patent abandoned.*

869. G. CHAMPNEY. "Improvements in reaping machines." Dated April 7, 1859.

Here the corn is cut by a series of circular saws driven by straps and pulleys from a suitable driving spindle in the body of the machine. The cut corn falls on to an endless inclined travelling sheet which conveys it from the cutters towards the hind portion of the machine where a receiving box or "type" is placed into which the corn collects. *Patent abandoned.*

870. J. LAKIN, jun. "A new or improved agricultural drill." Dated April 7, 1859.

The essential feature of this invention is a vibrating spout which delivers the manure by a side-long delivery. *Patent abandoned.*

871. J. GARRETT. "Improvements in the construction of goblets, jugs, and other like articles." Dated April 7, 1859.

This consists in mounting the bowl in a setting of metal which will thus be protected from liability to injury, and may be readily removed to facilitate the cleaning of the bowl. This metallic portion constitutes the foot and handle, and the bowl is secured by making it fit at bottom on to a projection or into a holder in the metallic foot, and causing the upper part of the handle (which is connected to the foot) to clip the edge of the bowl. *Patent completed.*

872. J. RAWLINGS. "An improved construction of boot-tree." Dated April 7, 1859.

The patentee constructs a boot-tree capable of contracting to receive the boot, and of being expanded and retained in that position while the boot is being cleaned. This boot-tree is fastened to any fixed point. *Patent abandoned.*

873. J. T. PITMAN. "Improvements in the construction and use of fireworks for signals." (A communication.) Dated April 8, 1859.

This invention is not described apart from the drawings. *Patent completed.*

874. W. H. SMITH. "Improvements in the construction of cartridges, and in fire-arms for using the same." Dated April 8, 1859.

This consists in making a cartridge with several compartments in which the powder is deposited; these are separated from each other by interposing discs of metal so that the powder shall ignite and explode in each compartment in succession, and give successive impulses to the missile. It also consists in constructing the interior of the barrel with cutting or sunken grooves of different depths, but in the same continuous line, the deepest being at the breech. At a proper distance the depth diminishes, and so on successively as many times as there are chambers in the cartridge for the purpose of receiving the ends of these projections, and allowing them to proceed their intended distance without obstruction. The depth of the groove being lessened at a given point raises a barrier against which the wings strike, and the percussion powder is exploded, igniting the powder in the next chamber. *Patent abandoned.*

875. J. BINDLEY and J. L. HINKS. "Improvements in rotatory steam-engines and pumps, a portion of which improvements may also be applied to the bearings of shafts or axles, and other rotating bodies." Dated April 8, 1859.

The patentee claims, 1, a rotatory steam-engine or pump consisting of two concentric drums, the annular space between the said drums being closed on one side by a rotating vane carried by the smaller of the two drums, the steam or water being admitted and cut off by the descent and ascent of a slide valve, the ascending motion of which slide-valve is affected by the same, and the descending motion by its own weight. 2. Making the bearings of rotatory steam-engines and pumps in four pieces, the said pieces being made to contract upon the neck of the shaft by the action of wedges and screws. *Patent completed.*

876. W. CAMPIOR. "Improvements in machinery for the manufacture of looped fabrics." Dated April 8, 1859.

This consists in the arrangement and combination of a moveable needle bar and needle presser and looped hooks and sinkers and thread carriers, which are moved by cams and by which greater speed is obtained than heretofore. *Patent completed.*

877. W. WHEELDON. "An improvement in looking-glasses and mirrors." Dated April 8, 1859.

The object here is the ornamenting and increasing the reflective powers of looking glasses and mirrors, and consists in frosting, roughing, or obscuring, and cutting or carving an ornamental border on one or both sides of the plate, and afterwards silvering the same on the side on which the design is produced. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Aug. 31, 1859.

1962. G. S. Fleming. Improvements in candles for the purpose of indicating time, and the facility of lighting the same.

Dated Sept. 28, 1859.

2178. G. Addenbrooke. Improvements in raising and lowering boats and other vessels from one water level to another, applicable in inland navigation.

Dated Sept. 28, 1859.

2198. E. T. Simpson. Improvements in apparatus for condensing distilled fatty matters.

Dated Oct. 6, 1859.

2274. E. O'Connell. Improvements in apparatus for supplying liquid nourishment to infants, invalids, and others, and for warming or heating the same.

Dated Oct. 7, 1859.

2288. J. Dixon. Improvements in apparatus for supplying water to water-closets.

Dated Oct. 10, 1859.

2302. G. Davies. Improvements in the manufacture of paper, pasteboard, and cardboard. (A communication.)

Dated Oct. 13, 1859.

2332. A. and J. Holden. Improvements in machinery used in washing, dyeing, sising, and drying yarn and thread.

2334. W. Prosser. Improvements in apparatus employed in the production of light.

2336. W. Burgess. Improvements in reaping and mowing machines.

Dated Oct. 14, 1859.

2339. C. Collins. Improvements in the manufacture of grease for lubricating the axles of railway and other carriages, the journals of machinery, and for other like purposes. (A communication.)

2342. J. P. Henderson. Improvements in stop cocks or valves.

2343. G. Price. Improvements in locks.

2344. J. Varley and J. Crowther. Improvements in steam-engines and boilers.

2346. G. Goldsmith. Improvements in gas meters.

2348. H. W. C. Wise. An improved domestic apparatus for making tea, coffee, and other such like beverages.

Dated Oct. 15, 1859.

2350. H. Chapman. An improved self-acting safety railway break.

2352. J. Fernihough. Improvements in the construction of steam-boilers and apparatus connected therewith.

2354. J. H. Johnson. Improvements in machinery or apparatus for breaking stones. (A communication.)

2358. N. Montanari. An improved apparatus for aiding children in learning to walk.

2360. J. Elder. Improvements in steam and other engines.

Dated Oct. 17, 1859.

2362. W. K. Hall. Improvements in apparatus for manufacturing cotton wadding. (A communication.)

2364. S. Newberry and H. Moore. Certain improvements in looms for weaving.

2366. W. E. Newton. Improvements in rotary steam-engines. (A communication.)

2368. W. Norton. Improvements in kilns for drying grain.

2370. J. Thom and A. Kennedy. Improvements in looms for weaving.

2372. R. A. Brooman. Improvements in electro-magnetic engines, and in apparatus connected therewith. (A communication.)

2374. W. Tillie. Improvements in sewing machines.

Dated Oct. 18, 1859.

2378. A. W. Williamson. Improvements in obtaining extracts from poppies.

2380. J. Higgins and T. S. Whitworth. Improvements in machinery or apparatus for preparing and spinning cotton and other fibrous materials.

2382. W. E. Newton. Improvements in machinery used for spinning silk, wool, or other fibrous substances. (A communication.)

2384. H. Hirsch. A new propeller for ships.

Dated Oct. 19, 1859.

2386. J. H. Banks. Improvements in machinery for boring, cutting, moulding, and carving wood, stone, and other materials.

2392. C. Seton. Improvements applicable to the wheels of carriages generally for the purpose of reducing the draught thereof.

2394. G. Hart. Improvements in the manufacture of hats.

2396. J. and H. Bruckshaw and W. S. Underhill. Improvements in machinery for elevating grain or other similar substances.

Dated Oct. 20, 1859.

2400. E. T. Hughes. Improvements in machinery or apparatus for compressing and making caps for cartridges. (A communication.)

2401. R. A. Brooman. A cryptographic machine or apparatus for carrying on secret correspondence. (A communication.)

2402. P. A. Godefroy. Improvements in the construction of submarine cables.

2403. F. Nivelle. Improvements in sewing machines.

2404. J. Hodgson. Improvements in building ships and vessels.

2406. C. Hanson. Improvements in fire-arms and ordnance.

Dated Oct. 21, 1859.

2406. J. Musgrave. Certain improvements in steam-boilers.

2407. J. H. Green. A composition for coating metals and other substances for various purposes.

2408. J. T. Pitman. An improved mode of converting cast iron into soft malleable iron without change of form. (A communication.)

2410. G. T. Bousfield. Improvements in apparatus for steering vessels. (A communication.)

2411. T. S. Pridesaux. Improvements in the construction of ships and rafts.

2412. W. Maltby. Improvements in refining oil.

Dated Oct. 22, 1859.

2414. P. Jones. Improvements in machinery or apparatus for suspending, carrying, and laying-down

paper, woven fabrics, paper-hangings, and all kinds of flexible materials during and after the process of drying and also for giving a continuous positive motion to the suspending rods or spindles.

2415. G. B. Mill. Improvements in pressure-regulating apparatus for gas burners.

2416. W. Fox and J. Willis. Improvements in the manufacture of umbrellas and parasols, part of which improvements is applicable to other purposes.

2417. R. A. Brooman. A method of preparing inoxidizable oils and fats to be employed as lubricating substances. (A communication.)

2418. W. Brookes. Improvements in machinery or apparatus for preparing wool and other fibrous materials. (A communication.)

2419. S. Beardmore. Improvements in electric telegraphs.

2420. W. Thorold. Improvements in apparatus applied to locomotive engines for condensing steam.

2421. J. Dahlke. Improvements in the preparation of charcoal and its application to the purification of water and the preservation of organic matters, and in apparatus connected therewith.

2422. F. Wrightson. Improvements in purifying coal gas, and in utilizing compounds obtained in purifying coal gas.

2423. F. N. Clerk and C. Thomas. Improvements in clevers and choppers.

Dated Oct. 24, 1859.

2424. A. L. Dowie. Improvements in gas burners, and in pressure-regulating apparatus for the same.

2426. G. Holden. Improvements in machinery for spinning cotton and other fibrous substances.

2427. A. C. Bertrand. Improvements in the manufacture of herbal cigarettes.

2428. R. A. Brooman. Improvements in daylight and other reflectors, and in the method of supporting lamp reflectors. (A communication.)

2429. M. Fitzpatrick. Apparatus to be applied to the prevention of accidents on railways, called "parachoc."

2430. R. Seager. Improvements in compounds of india-rubber and gutta-percha.

2431. W. E. Newton. Improvements in the construction of ships or vessels. (A communication.)

2432. W. E. Newton. Improvements in paddle-wheels. (A communication.)

Dated Oct. 25, 1859.

2433. H. S. Rosser. Improvements in electric telegraph cables, and in the mode of obtaining signals.

2437. W. A. Matthews. Improvements in springs.

2439. E. Ellis. Improvements in the manufacture of lace, and in apparatus employed therein.

2441. E. S. Tebbutt. An improved manufacture of elastic fabrics.

Dated Oct. 26, 1859.

2443. W. Clark. Improvements in the preparation and application of baths or bathing media, and in apparatus employed therein. (A communication.)

2445. J. Z. Kay. Improvements in gas meters and in apparatus for maintaining or preserving the levels of liquids.

2447. J. H. Paterson. Improvements in shirting cloths and in shirts.

2451. C. E. Wilson and H. G. Hacker. Improvements in machinery for the manufacture of chenille.

2453. T. Whitby and W. Dempsey. Improvements in ordnance and fire-arms.

Dated Oct. 27, 1859.

2455. C. Stevens. A machine for scouring and polishing floors and decks of ships. (A communication.)

2457. E. H. Rascol. A new implement for cleansing of the plates, dishes, and other table or kitchen utensils. (A communication.)

2459. R. M. Ordish. Improvements in railway fastenings.

2461. R. A. Brooman. Improvements in the preparation of red colouring matters or dyes. (A communication.)

2463. H. Cowan. An improvement in waistcoats and certain other articles of wearing apparel.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Nov. 8, 1859.)

- 1528. J. Roberts. Filters.
- 1533. G. and T. H. Wrigley. Self-acting mules.
- 1543. G. Hall, jun. Reaping machines.
- 1546. W. and J. Wray. Reaping machines.
- 1548. T. Wight. Cast metal pipes.
- 1553. E. Francis. Packing grocery.
- 1558. L. Boigeol. Twisting fibres.
- 1579. R. W. Morville. Window sashes. (A communication.)

1589. H. C. and J. C. Howells. Registering the number of passengers.
 1593. J. McIntosh. Driving belts.
 1594. A. Beaulieu. Crinolines. (A communication.)
 1607. L. Schwartzkopf and F. C. Philippson. Steam hammers.
 1612. F. A. Le Mat. Ordnance.
 1614. R. O. Rapior. Rolling plates.
 1618. J. H. Johnson. Knitting frames. (A communication.)
 1620. W. H. Dawes. Iron.
 1622. F. A. Le Mat. Fire-arms.
 1636. M. Henry. Overshoes. (A communication.)
 1640. W. Cotton. Looped fabrics.
 1644. R. Mushet. Projectiles.
 1655. R. Mushet. Metallic alloys.
 1674. R. Mushet. Metallic alloy.
 1707. Earl of Caithness. Permanent way.
 1747. E. Hunt and H. D. Pochlin. Resin.
 2069. E. J. Mallett. Axles.
 2152. R. Davidson. Holders for liquid or air.
 2170. R. Kay. Textile fabrics.
 2181. W. Airey and J. Clayton. Preparing for spinning.
 2251. J. Thompson and J. Thompson, jun. Salt.
 2263. W. E. Newton. Fire-arms. (A communication.)
 2314. A. V. Newton. Clarifying saccharine solutions. (A communication.)
 2318. W. Day. Rotary steam-engine.
 2323. T. Rothwell. Well-holes.
 2343. G. Price. Locks.
 2363. W. K. Hall. Wadding. (A communication.)
 2411. T. S. Prideaux. Ships and rafts.
 2419. S. Bearlmore. Electric telegraphs.
 2441. E. S. Tebbutt. Elastic fabrics.
 2445. J. Z. Kay. Gas meters.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Nov. 4, 1886.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS IN VITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

BALLAST LIGHTERS AND BARGES, Trinity House.—For the building and repairing of the ballast lighters and barges belonging to the Trinity House. The necessary printed forms, and every particular, at the Ballast Office, Trinity House, where tenders, November 11.

DREDGING MACHINE AND SCREW HOPPER BARGES, Newcastle.—For the construction of a dredging machine and three hopper barges for the Tyne Improvement Commissioners. Plans and specifications at the engineer's offices, Town Hall-buildings, Newcastle-upon-Tyne. Tenders addressed to the chairman of the commissioners, on or before Dec. 13.

CORPORATION WATERWORKS, Bradford.—The Waterworks Committee of the Bradford Corporation will meet at their offices in Bradford, on Tuesday, the 29th of November, at 11 o'clock, a.m., for the purpose of receiving tenders or proposals for the following works:—The excavating for building and completing of a portion of the main aqueduct or conduit for conveying water to the town of Bradford, commencing at Randed Beck, in the township of Burnall, and terminating at the south end of a certain tunnel now in course of construction called Baden tunnel, in the township of Baden, with a certain branch conduit in the township of Draughton, such conduits being of the aggregate length (including the laying of certain iron pipes for supplying the village of Burnall and about 675 yards of 21-inch pipes for crossing the valley of the Baden Beck) of about 7½ miles. Plans and specifications, &c., of Mr. John W. Leather, civil engineer, Leeds.

REFRIGERATORY, Dalby, near Doncaster.—For the works necessary in the erection of the West Riding Refractory for Glrls. Drawings, &c., to Mr. Haughton, Hyde Park, Doncaster. A large quantity of building materials on the site will have to be taken by the contractor, and used as far as applicable in the proposed buildings. Tenders to Nov. 29.

SCUTCHING ROOM, Bolton.—For the erection of a scutching room, a mixing place, and a warehouse at Belmont Mills. Plans, &c., Mr. James Lomax, surveyor, 8 Foid-street, Bolton. No date given.

COALS, Nary.—For 2,000 tons of South Wales coals monthly, to be delivered into store at Her Majesty's Naval Yard at Malta for six months from 1st December. The commissioners having the power to increase the monthly proportion to be shipped after 1st January next to any quantity not exceeding 4,000 tons in each month, if required, on one month's notice to the contractor. Conditions of contract and form of tender may be seen at the office department of the Storekeeper General of the Navy, Somerset-place. Tenders must be addressed to the Secretary of the Admiralty, and delivered at Somerset-place, accompanied by a letter signed by two responsible persons, engaged to become bound with the person tendering in the sum of £5,000. Tenders and attendance 15th inst. at 2 o'clock.

COAL, East India Company.—For the supply of 3,000 tons of coal for steam navigation, to be delivered into store at Madras. Tenders, to 22nd November, or forms to be had at the Marine and Transport Department in the India office, they must be left at the Secretariat office.

COAL, India Board.—To supply 3,000 tons of coal for steam navigation to be delivered at Bombay, or any of the under-mentioned ports, viz.:—West Hartley, Longridge's West Hartley, Bryant's Bedside West Hartley, Ravensworth West Hartley, Donnasholm's Hartley, Hartley's Hartley, Stewart's Wall-end Steam, Hartlepool West Hartley, or Samuelson's real old Gamber (Oak's colliery) Hard Steam Coal. Forms of tender to be had at the Marine and Transport Department in the India office, with conditions annexed. Tenders, before 11 forenoon, Nov. 13, at the Secretariat office.

DEAR CONTRACTORS, St. Giles, Cumberland.—For the purchase, collection, and removal, of all the ashes, cinders, rubbish, dust, breeze, refuse, flth, soil, &c., in the several roads of the above parish, between Dec. 1, 1886, and November 30, 1886. Separate tenders for each of the six wards. The necessary draft, contract, and bond, to be seen at the Vestry Clerk's office, Vestry Hall, Cumberland. Tenders at the Hall, Nov. 11. Personal attendance necessary; and the successful tenderer must deposit £5.

ROADS, Worcester.—For making the intended new roads over about seven acres of land at the top of Barbours-terrace, and laying down the culverts connected therewith. Plans, &c., and conditions at the office of Mr. Henry Day, surveyor, Foregate-street, Worcester. Tenders to Nov. 12.

ROADS, Waterhead to Westmoreland, Ambleside.—For the widening, improving, and diverting the road leading from Waterhead to the south entrance of the town of Ambleside. Plans, &c., the office of Mr. Webster, land surveyor, Rindal, who will meet intending contractors on the ground at 10 a.m., on Wednesday, Nov. 16, to point out the works and receive tenders, which must be in writing and under seal. The plan may be seen on application to Mr. Thomas Balderston, Ambleside.

SURVEY, Barnsley Union.—The guardians are desirous of contracting with two gentlemen, not being partners, for a new valuation (to be new in conformity with the Parochial Assessment Act) of the whole of the household property, mills, manufactories, collieries, gas-works, water-works, railways, and canals, in the township of Barnsley. And the guardians wish to contract with one valuer for a new valuation of the land in the said township. A recent survey has been made of the township, and the map may be used so far as the same may be applicable and correct. Contractors may tender either by commission, or for a fixed sum. The township contains about 2,200 acres of land, and 3,776 houses, warehouses, and other buildings. Tenders and testimonials to Mr. John Tyas, Clerk to the Guardians, to Nov. 21.

RAILWAY DRAUGHTSMEN.—For the Cape Town Railway and Dock Company. One experienced in station work, and the other in wrought and cast-iron work, are required by this company to sail for the Cape by the mail of the 6th December next. Applications, with copies of testimonials, and stating terms, to Mr. G. Latham Browne, managing director, 281 Gresham House, Old Broad-street.

TRAVELLER TO WIRE DRAWER.—One acquainted with the trade, and of good address, will be liberally dealt with. When not engaged in travelling, his services will be required in the counting-house. Applications personally or in writing, to Mr. John Caw, accountant, Halifax; or Messrs. Shackles and Sons, solicitors, Leeds.

TRAVELLER FOR A PLATE GLASS MANUFACTORY.—State where last employed, and the terms required. Address, Box L., 20 Post-office, Manchester.

TIN-PLATE WORKERS.—Eight or ten first-class men. Constant employment and good wages to steady men. Apply to Mr. T. Wright, Victoria Tin Works, Sackville-street, Manchester.

GAS WORKS MANAGER.—A person to take the entire charge of the Morecambe Gas Works, near Lancaster. His duties will be to undertake the manufacture of gas, lay down main and service pipes, and fixing meters, and other matters appertaining to works of this description. He will have a house on the premises rent free, and firing and gas. Applications with testimonials, and stating terms, to Mr. William Whitehead, secretary to the above company.

EXPERIENCED HANDS.—To fix galvanised corrugated iron, self-supporting, and other kinds of iron roofs. Address, with full particulars to previous engagements and references, M., 47 General Post-office, Liverpool.

FORGE MANAGER.—Application by letter, with full particulars of qualifications, age, and expectations, to Mr. Roberts, care of Messrs. Horn and Story, Grey-street, Newcastle-upon-Tyne.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 18, 1859.

EDUCATED FEMALE LABOUR.

It is far easier to sneer at the "rights of woman" than to show why the wrongs of woman should not be redressed. We Englishmen, to whom "home" is the sweetest and most precious possession, are too much in the habit of seeing in woman only the raw material for conversion into wives and mothers. We think of women as the attendants and helpers of men, and nothing more. Or if more, then only when

"Man is the hunter; woman is his game;
The sleek and shining creatures of the chase,
We hunt them for the beauty of their skins."

But in all this we men are wrong—stupidly, blindly, heartlessly wrong. Doubtless the great and primary office of woman is that of being man's "help-meet." But as doubtless this is not, cannot be, her only calling. To many a woman the hope of marriage never comes; to many more the dream of wedded life dissolves before its realisation is attained; to others, scarcely have the bridal bells ceased clashing ere the husband is tolled to his tomb; others put on with the weeds of widowhood the burden of providing for a numerous family; and so forth. On all sides we are surrounded by women whom God and Nature have cut off from man's immediate aid, and who by brain or hand must win, for themselves at least, their daily bread.

It would be rather late for us now to attempt to show how few are the means by which women thus circumstanced can at present obtain livelihoods. It is well known the one chief calling which is open to them—that of a governess—has gradually been so brought down that we have come to consider it but little, if any, superior to that of the humblest menial service; and it is equally well known that scarcely any other outlet for female activity has hitherto been deemed respectable. These facts have lately been much considered by the public, and many measures have been taken for bringing about a better state of things. The latest movements are, first, the establishment of "registers of woman's work," to be managed by committees of ladies, and in which may be registered the names of any ladies who wish to become candidates for remunerative employment in charitable institutions, as nurses in hospitals, matrons in workhouses, teachers or superintendents in industrial schools—likewise for those who desire to obtain situations as secretaries, clerks, or bookkeepers, while other kinds of employment will in all probability gradually suggest themselves in accordance with the needs of society; and, secondly, the establishment of a society for promoting the employment of women. The committee includes several ladies of title; Viscount Raynham, M.P., is the treasurer. A statement has been published in which various objections to the employment of women are answered. It appears also from this statement that it is the intention of the society to establish a large school for girls and young women, where they may be specially trained to wait in shops, by being thoroughly well instructed in accounts, bookkeeping, &c.; be taught to fold and tie up parcels, and perform many other little acts which a retired shopwoman could teach them. The necessity of politeness towards customers, and a constant self-command, will also be duly impressed upon them. Girls educated in this school would be capable of becoming clerks,

cashiers, and ticket-sellers at railway stations. It is also contemplated to establish workshops in connexion with the school, where the girls might be taught other trades—trades well suited to women, but now almost exclusively in the hands of men, such as printing and hair-dressing, for instance. As the means of the society increased so would the number of workshops and the variety of trades taught. No girl would be admitted to either school or workshop who did not bear a good character; nor, on leaving, would she be recommended for employment till she had passed such examinations as proved her to be competent for it.

This is all most gratifying; and in pursuance of the good work we would urge upon the promoters of these movements the immense importance of multiplying lady mechanics! We want all our men for our heavier trades, such as engineers, builders, shipwrights, blacksmiths, and so forth—trades to which we can never put woman; and we may very well hand over our lighter mechanical crafts to our poorer females. It is, of course, simply disgraceful to see the young women of our land forced by thousands into vicious courses for mere want of employment, while equal numbers of our young men are draining away their manly qualities behind drapers' counters, in hairdressers' rooms, and in scores of other occupations for which women would display equal, if not greater, aptitude; and although light mechanical trades are less obnoxious to man's manliness than such occupations as those just mentioned, they may doubtless be entrusted to women with advantage to both sexes.

There is one trade in particular for which woman is eminently adapted, which should not be lost sight of in this discussion, viz., that of the watchmaker. Mr. John Bennett, of Cheapside, has very nobly advocated the introduction of female labour into the watch-manufacture, at the expense of much personal odium; and so effectually has he stated his case, that some of those watchmakers who denounced his labours in this matter, are prudently bringing up their own daughters to the business. Mr. Bennett tells us, not only that women are in all respects competent to make watches, but that we British people are absolutely importing large numbers of women-made watches every year.

The Paris Exhibition must, he says, have opened the eyes of all but the wilfully blind to the startling fact, that quality, strength, and elegance considered, the Swiss are nearly 40 per cent. under our prices. "So striking was their 'superiority, except in our first-class watch,'" he remarks, "that I took my own eyes for a month through their principal manufacturing districts. There I found causes in active operation that explain the whole matter. 'From three leading manufacturers I learnt that 1,500,000 were made last year in the Neufchatel district, and this over and above the produce of the Geneva district. They declare, too, that their powers of production have doubled in the last seven years. The 'marvellous ingenuity of their tools and their 'skilful economy of labour fully confirm this statement.' So prosperous has been the handicraft of these intelligent mountaineers, that thousands of men and women engaged in the trade people all the hills and valleys far and wide, from the Val de St. Imier, in Berne, in the North, down below St. Croix, looking over the Lake of Geneva. Compare the thousands there, from north to south, with our manufacturers. Within the London district, including every dealer who professes and calls himself a watchmaker, we had in 1851 but 4,800 in the trade. And what is the result? That we have become

customers to these very Swiss for watches for our own use at home. Thousands of women are at this moment finding profitable employment at the most delicate portions of watchwork throughout the district round Neufchatel. The subdivision of labour is there wisely made so minute as to adjust itself precisely to the special capabilities of every woman's individual dexterity. It is impossible to believe that the women of London will do badly what the Swiss women are now doing so well. Thousands of the women of London, now in dire distress, have the power to equal and perhaps to outstrip their Swiss sisters in a rival race for an honourable and abundant means of subsistence. "I know the realization of my suggestions to be within their reach, and I believe," says Mr. Bennett, "there are few men of any worth who will refuse to join me in the wish that Heaven may grant that this desirable means of rescuing so many from their present misery may be speedily removed from the necessity of newspaper discussion."

We agree with Mr. Bennett; and if Viscount Raynham and his colleagues would do their work effectually, they should inquire closely into this watchmaking question, which lies ready to their hand. In their whole movement we wish them the most perfect success.

THE MEASUREMENT OF WAVES.

THE name of the late Dr. Scoresby has been associated more prominently than that of any other man with the subject of wave-measurement. His estimates of the heights and breadths of Atlantic waves have entered into many important discussions of late years, and have formed the basis of serious arguments respecting the dimensions of large ships and other great questions. The interest attached to his observations on this subject does not appear to have arisen from any extraordinary aptitude on his part, or from the possession by him of any special apparatuses for the purpose. Any other intelligent person accustomed to estimating heights and distances by the eye, or by the aid of simple mechanical expedients, could have done all that Dr. Scoresby ever did, or ever pretended to do, in the way of obtaining data respecting the dimensions of waves. But, strange to say, of all the thousands of clever mechanical men who sail the seas in pursuance of their various avocations, only here and there one is found to bestow a little attention to this very interesting topic. With this fact before us we cannot but be grateful for the pains which Dr. Scoresby repeatedly took to enlighten us, and especially for the ample information which he has afforded us in his journal of his voyage round the world in the Royal Charter, to which we drew attention in our last number.

It may be of some interest to describe the methods adopted by him on that occasion for obtaining scales of measurement for the height, distance of the undulations, and velocity of the waves. They were, in the main, similar to those which he adopted in his inquiries on the waves of the Atlantic, the results of which were communicated to the British Association at its meeting in Edinburgh, in 1850. In writing of the great gale which overtook the ship on her voyage to Australia in April, 1856, he says: "As the ship was scudding directly before the gale, and was astonishingly steady and upright for considerable intervals of time; and as, notwithstanding her great length, she found an ample extent for being evenly cradled, as to her general bearings of flotation betwixt wave and wave, it was easy to find a scale, as I did, by ascending the mizen rigging, by which the

"height of the ordinary and highest waves, as they might be found to correspond with or to intercept the sea horizon, could be satisfactorily measured." In this way, ascending by steps, after a first position taken at a guess, he found that with his feet on the seventh rattling he had the line of elevation of the prevalent wall-formed waves. But he attained the interval between the sixteenth and seventeenth rattling before he obtained the measure of elevation of the waves of the maximum class. Of these, several rose still higher, but he kept his position till one or more of great breadth and solidity of mass was seen rising above the horizon along an unbroken extent of some hundreds of feet. The height of the eye of a man of Dr. Scoresby's stature in this position above the eye of a similar person on the saloon deck below was $15\frac{1}{2}$ ft., and the height of view on the deck, as otherwise estimated, was about 23 feet; the sum of $38\frac{1}{2}$ feet was therefore obtained for the maximum class of the prevailing waves. But, as the wave specially noted was more than two feet higher than the horizontal level, its actual height could not have been less than 41 or 42 feet. But from the station of observation several incidental peaks or points of waves, often thrown up by the intersections of cross seas, were observed to exceed considerably the ordinary maximum, whilst the tops of breaking crests might be seen rising still higher, indicating an ultimate maximum which could hardly be less, the Doctor thinks, than 50 feet.

The next points of inquiry were the distance of the waves from crest to crest, and their general velocity. These measurements, however, from the want of regularity in the sea—a peculiarity of the waves of the Southern Ocean—could not be so conclusively determined as the height; but proximately, the results were very satisfactory as compared with similar investigations in the North Atlantic. The time occupied by the waves in successively passing the ship was found when the ship's rate of going was about 12 knots to be generally (in the case of distinct series of heavy rollers) about 18 seconds. With this fact for his guidance, Dr. Scoresby ascended the main rigging to a convenient height, where, being over the centre of the ship, he could observe when the crest of a wave went beneath the stern and when it emerged from beneath the bow. This observation frequently repeated gave him a pretty regular result (as shown by the counting of seconds with a watch at his ear) of nine seconds for the interval occupied in the passage of the ship's length, say 320 feet, and of nine seconds more for the arrival at the stern of the following wave.* This indicated plainly a distance of just about twice the ship's length, or 640 feet for the prevalent space, transversely to their axes, from crest to crest of the waves.

A tolerably correct estimate of the velocity of waves became fairly deducible from these data. A space was seen to be passed over by any particular wave, with reference to the ship's position, of about 640 feet in 18 seconds; but this was of course too small by the proportion of the ship's retreat from the wave, or her advance in the same direction during the same interval. Taking the geographical mile at 6,075 feet, we find the quantity of 1·69 feet per knot to be due to each second of time; or 20·28 feet per second as the ship's progress when going 12 knots. This multiplied by 9, the number of seconds occupied by the sea in running the length of the ship, gives a product of 182·52 feet for the advance of the ship in the same

line and within the same interval. To the velocity of the waves, therefore, reckoned on the ground of the ship being stationary—say 320 feet in nine seconds, or 35·56 feet per second—we add the advance of the ship, or 20·28 feet per second, in the same line of direction, and thus obtain for the actual velocity of the wave 55·84 feet per second, or 33·9 geographical miles per hour—a result the more satisfactory seeing that in making a like experiment on very high waves (30 feet) measured in the North Atlantic, in 1847, Dr. Scoresby obtained for these waves a distance from crest to crest of 559 feet, and a velocity of 32·67 miles per hour.

THE EXHIBITION OF 1862.

SIR THOMAS PHILLIPS, the Chairman of the Council of the Society of Arts, in his opening address, delivered on Wednesday evening last, announced the intentions of the Council in reference to the Exhibition of 1862. Before repeating the statements made by him, it may be well to go with Sir Thomas over the preliminary facts of this matter.

The subject of international exhibitions of works of industry and art having been brought under the notice of the Council of the Society in the session of 1858, received their careful consideration, and occupied much of their time in that as well as in the following session, and in the address of Sir Thomas Phillips's predecessor at the beginning of last session, and in the report of the Council presented at its close, a narrative of the proceedings of the Council in relation to the subject was presented to the members of the Society. The Council having bestowed on this question that grave attention which the importance of the subject deserves, resolved, on the 14th of April, 1858, that the Institution of Decennial Exhibitions in London, for the purpose of showing the progress made in industry and art during each period of 10 years, would tend greatly to the encouragement of arts, manufactures, and commerce, and that the first of these exhibitions, which it was then intended to hold in 1861, should consist of works selected for excellence, illustrating especially the progress of industry and art, arranged according to classes, and not countries, and should comprise music and painting. The investigations of the Council led them to conclude that an international exhibition in 1861 would elicit even more valuable results than had been achieved in 1851.

While the Council was actually preparing to originate the exhibition, hostile gatherings, of which Italy was the centre and object, threatened to involve the principal continental States in active and protracted warfare. The probable influences on an international exhibition of the unexpected interruption to the peaceful relations of the States of Western Europe led the Council, in the month of May last, to determine that the international exhibition proposed to be held in 1861 should be postponed to a more favourable opportunity. That decision was arrived at by the Council with much regret. "An exhibition," said Sir Thomas, "which should present an adequate picture of the progress of arts and industry, when employed in extending the blessings of peace and promoting the progress of civilisation, might prove of special utility at a season of strife and warfare; and even if war were again to interrupt the peaceful intercourse of continental States, it is obviously within the power of the United Kingdom, including the colonies and dependencies of the empire, to produce an exhibition deserving of national patronage. The progress of art and industry is not suspended, however much it may be

"interrupted by actual warfare, and the loom and the forge may pursue their wonted activity even amid the din of arms." The past history and present position of our country alike impose on Englishmen, continued Sir Thomas, duties which cannot be evaded with dignity, and they surely may decide themselves whether and when they will hold exhibitions of art and industry, although warlike preparations may seem to occupy other nations. The war in Italy having terminated, the Council have anxiously resumed the consideration of this important subject, and, notwithstanding the present aspect of continental affairs, which they do not regard as the most favourable to arts, manufactures, or commerce, it is nevertheless the intention of the Council, interpreting aright, as they believe, the feelings of their countrymen, to originate measures for carrying into effect an international exhibition of works of art and industry, to be held in 1862; and they propose to invite the manufacturers, merchants, public companies, and other capitalists willing to promote such an exhibition, to unite in raising a guarantee fund, not less in amount than £250,000, to be vested in trustees whose position, character, and qualifications will secure the confidence of those capitalists who are prepared to share the responsibility of the undertaking. It is the intention of the Council that full and absolute power to originate and conduct the exhibition shall be vested in such trustees, and that the permanent buildings which may be found necessary shall vest in the Society of Arts, in order that such buildings may be devoted to future exhibitions, and when not so occupied may be employed for purposes tending to the promotion of arts, manufactures, and commerce. The trustees will doubtless seek the assistance of Her Majesty's Government in order the better to obtain the friendly assistance of foreign Governments and secure the co-operation of foreign exhibitors, and otherwise promote the success of the exhibition of 1862, and will also apply to the Royal Commissioners for the Exhibition of 1851 to grant a convenient portion of the ground purchased at Kensington out of the surplus funds of the Exhibition of 1851 for the next and future exhibitions.

THE DRAINAGE OF LONDON.

IN November last, we drew attention to an interesting publication by Mr. Charles Glassford, of Greenwich, entitled "London Sewage, shall it be Wasted, or Economised? Being a Plan for the Collection and Treatment of the Fæcal Matter of Towns, for Purifying the Sewers and Rivers, and Removing the Chief Impurities, which render them Dangerous to the Health of Communities, with especial and immediate reference to the Metropolis, the River Thames, and the Board of Works' Main Drainage Scheme." Since that period, several modifications of Mr. Glassford's plan have been suggested, which considerably affect the results. Before entering upon these, it may be advisable to recapitulate very briefly the chief points of the plan, as detailed in the above publication. Mr. Glassford proposed, first, to collect the excrementitious matter directly from the water-closet, with such a limited and measured quantity of water as should make the subsequent operations for the recovery of the fertilising matter economically practicable. Second, to convey the excreta and water through a system of pipes and sunk vessels to large reservoirs at a distance from town, where it is to be deodorised, and neutralized with oil of vitriol; then allowed to subside for a few hours. The effect of this treatment will be, that the whole of the nitro-

* The length of the Royal Charter's keel was 308½ feet; length over all 336 feet. But he estimated, as he believed, a medium of the rake and overhang, and therefore took about a mean measure or estimate of 320 feet for the ship's length.

genous matter of the urine—the most valuable constituent—is saved, and fixed in the form of sulphate of ammonia. Third, the liquid portion is pumped into a system of boilers and evaporating vessels, where it is concentrated into a crystalline mass, which is chiefly sulphate of ammonia, with all the other valuable salts contained in the urine, the agricultural value of which Mr. Glassford proposes now to reckon at £10 per ton. The more solid portion collected by subsidence in the reservoirs is pumped up separately, and conveyed into a series of presses, or filtering machines, which separate the solid and insoluble portions from the liquid, and finally present it in an almost dry, solid, and inodorous cake, containing the organic matter and insoluble phosphates of the solid excreta, the agricultural value of which he reckons at £4 per ton.

These values are obtained by estimation of the market prices of the constituents, in the way usually resorted to by agricultural chemists in their estimation of guano and other manures. Mr. Glassford has estimated that the yield of these manurial products from the London excreta would amount to 136½ tons daily, from the liquid part; whilst that from the solid part would amount to seventy tons daily. In his estimate for London, he assumed £15 per ton as the value of the urine salts, but as this has been objected to as too high, he has decided now to assume £10 per ton nett price, after paying charges of delivery, agency, discount, &c. The other manure is not, he considers, too high at £4 per ton nett, after paying these charges. The result at these prices would thus be:—

		Per annum.
For 136½ tons urine sulph. of ammonia	per day, at £10 per ton ...	£497,312
„ 70 tons solid organic manure, per day,	at £4 ...	102,200
		£599,512

or as nearly as possible six hundred thousand pounds per annum, after paying all agency, carriage, and discount charges. "I have estimated the annual costs of materials, such as coals and vitriol, and of labour, at nearly £237,000, and of interest on cost of necessary works, tear and wear, &c., at £170,000, which sums together amount to £407,000 of total expenses of all kinds, and, allowing very liberally for every possible charge, leaves a sum of nearly £200,000 annual profit; a sum which would be found of enormous advantage in carrying out the improvements—useful and ornamental—so urgently required in this our crowded metropolis."

It has been objected to the plan that Mr. Glassford proposes to use a water-closet apparatus which is too complicated, which would be likely to get out of order, and that the quantity of water proposed by him is too little. To these objections he now replies:—First, that the ordinary earthenware pan and syphon trap, so extensively and universally used, would answer all the purposes required, so that there need be no alteration whatever in that part of the present closet arrangements; the only alteration required would be the substitution of a regulator valve instead of the usual stopcock, or other water supply arrangement. This would avoid great expense, and would be equally if not more efficient than that previously proposed. Second, instead of limiting the supply of water to the closet pan to twelve ounces per discharge, he would now allow any quantity up to one gallon per delivery per individual—a quantity which he considers far beyond what would, under any circumstances, be required; but in this case—as the quantity of water to be removed, collected, and evaporated, is greatly increased, the cost of apparatus, fuel, and labour would also be

increased, whilst the material products would remain the same—the profits per annum would be diminished. "For each addition of twelve ounces of water thus employed in the closet, there would be an addition of about £10,000 to the cost of apparatus (works), and a reduction of about £3,150 from the profits, so that the employment of one gallon of water per individual (or per delivery in closet) would have the effect only of reducing the annual revenue by about £35,000." As to the objections which may be made in reference to the mechanical difficulties of the scheme, Mr. Glassford apprehends no difficulty that he would himself (although not a civil engineer) feel unwilling to undertake. In this country especially, as he says, we should be under no fear of easily overcoming any difficulties of a mechanical kind.

As the best method of determining the worth of any scheme is to put it in practice, Mr. Glassford earnestly urges the advisability of making a trial on, say, 500 to 1,000 dwelling-houses, grouped together in the same locality, so that all the products could be economically conveyed and collected together at a short distance, and there operated on; and we would gladly support him in this request. The operations can be conducted upon any quantity and upon any scale, so as to yield results which would amply test the value of the scheme, and enable a clear and practical judgment to be formed. To do all this, from one to two thousand pounds would be amply sufficient, and in a few weeks from the commencement the experiment would be in full work and yielding results. "I would be glad to assist with my services," says Mr. Glassford, "in carrying out the plan and bringing it to an issue."

"If we consider for a moment," says Mr. Glassford finally, "the vast sums of money which will unavoidably be absorbed in executing the very gigantic sewage works now in course of formation throughout London, which may absorb more millions than is now contemplated, besides the large annual sum required to keep the whole in good working order—if we consider, also, the number of years which must elapse before these works are completed—and if we consider, also, that fertilising matter (worth to our agriculturists a million sterling per annum), according to all our highest scientific authorities, including Liebig, Hofmann, and others, is still, after all this great expense and years of delay, only to be thrown away into the Thames, a few miles lower down the stream, without the certainty of relief from the nuisance or the shadow of a possibility of any return being ever obtained for all the outlay and annoyance, we shall have a clearer perception of the enormity of this Main Drainage Scheme."

We need hardly add that these views are our own. Mr. Glassford's proposals are consistent with good sense and the soundest science, and if our Metropolitan officials are not wholly blind they will lose no time in testing them, at least upon a small scale.

THE STOKE-HOLES OF STEAM-SHIPS.

No class of men suffer more from an overheated atmosphere than stokers, especially when they are employed in steam-vessels, and yet there is none to whom relief can be more readily and advantageously given. The stoke-holes of all steam-vessels may be kept at within 5° of the outer atmosphere at an almost nominal expense, and the means of doing this are attended by other advantages.

If our readers will consult a paper read before the Institution of Civil Engineers on the

14th November, 1854, No. 917, by Mr. William Woodcock, they will find the subject is there fully explained. The *modus operandi* is simply as follows:—Place immediately underneath the fire-bars two Venetian blinds, made of hoop iron, the bars lying horizontally and parallel to each other in the direction of their length, and inclined at an angle of 45° to the horizon in the direction of their width. The bars of the two sets must be inclined in opposite directions, and must be so close together that a vertical straight line cannot pass between any adjacent pair of them, and yet far enough apart to allow all cinders to fall freely through them. This device will keep the air in the ash-pit cool. Next, fasten upon the inner face of the fire-door a box made of angle iron, and projecting about an inch and a half into the furnace when the door is closed. Let this box be fitted with a few thicknesses of wire gauze, Nos. 8, 10, and 12, lying close together against its fire front, and leaving a space of at least one inch opening in the box between the gauze and the inner front of the door. Further, let all that part of the door which is within the box be drilled as full as possible of ½-inch holes, and it will be found that the door will by these means at all times be kept cool. The merits of this invention belong to Mr. Burney, of Battersea. We have now only the bulk-head of the boiler and the smoke-box doors to deal with. In front of these, and at one inch distance from them, secure, so as to open and close with the doors, a plate of iron or zinc; the latter will be better, as this plate must not be painted. Let the upper part of the one inch opening communicate directly by a pipe or otherwise with the deck. No heat will then escape into the stoke-hole from the boiler or from the smoke-box, and an upcast will be established over their front which will draw a supply of fresh air into the stoke-hole from any convenient source, whether the vessel is in motion or at rest, and the third and last source of heat in the stoke-hole will thus be cut off. This is all that has to be done. It involves the infringement of no patent-right, and can be arranged for a very trifling expense by any intelligent engineer.

Much has been written upon the combustion of smoke, and the respective merits of hot and cold air. The truth may be, that both are required. The above arrangement, if properly carried out, will be the most perfect smoke consumer, or rather smoke preventer, known. It will also save some small per-centage of fuel. Cold air is required to enter through the bars in order to give direct to the fuel the largest amount of oxygen in the smallest space; this the keeping of the ash-pit cool provides for. Upon this all are agreed. Warm air must also, many believe, be administered to the gases distilled from the coal, as otherwise they may be reduced below their "flame points" of heat; this is done by the respirator in the door, from the fact of the air passing through it having to impinge upon the heated wire gauze. No valve or regulator is wanted, as the fine wire gauze is found to check the supply when but little air is wanted, and to admit a large quantity when that is required, i.e., directly after firing, and when the bars are covered with fuel.

We claim no novelty for these suggestions, the credit of which is mainly due to Mr. Woodcock, the managing engineer of the London Warming and Ventilating Company. We simply confine ourselves to recommending them to the notice of those engineers and owners of vessels, many of whom are unhappily content to keep their stokers at work in temperatures which no human constitutions can long withstand.

Literature.

Journal of a Voyage to Australia and round the World for Magnetical Research. By the Rev. W. Scoresby, D.D., F.R.S., &c. Edited by ARCHIBALD SMITH, Esq., M.A., F.R.S., &c. London: Longman, Green, Longman, and Roberts. 1859.

[SECOND NOTICE.]

In our last number we promised some extracts of interest from this work. The first shall be upon THE FORM OF THE ROYAL CHARTER.

"In regard to pitching and 'sailing,' the action of the ship was equally remarkable, both for the easiness of the motion and the smallness of the inclination of the keel from the horizontal level. A forty feet wave, on its entrance below the stern or counter of the ship, whilst the bow was exactly in the lowest or most depressed portion betwixt crest and crest, should raise the stern, as from the simplest view of the case it might seem, to at least its own elevation, or give an angle of inclination to the keel of about 7°; but no such measure of pitching or 'sailing' motion was ever observed—probably not above half as much. For in no instance, in scudding, did I ever observe the bow of the ship plunge nor the stern rise to anything like the position apparently due to the elevation of the passing waves. The action, indeed, was obviously of this nature: from the admirable adjustment of the ship's lines of construction forward and aft, the loftiest wave on its reaching the stern-post below exerts its lifting tendency, not abruptly or suddenly, as where the quarters are heavy and the run thick, but very gradually, so that the disturbing force, passing beyond the place of greatest influence before its due action is realised, becomes modified and reduced. These principles are no doubt in operation in every tolerable model of marine architecture, but not to the degree of perfection in which the tendency to assume horizontality of position, and to receive the least possible disturbing effects from the most formidable disturbing causes in the action of rough, irregular, or heavy seas, has been attained in the modelling and building of the Royal Charter; and whilst similar results in kind will be found to have been obtained in very many or most of the scientifically constructed and splendid clipper and other first-class ships of this important age, I should much doubt whether in any single instance the approach to perfectness of the model of the Royal Charter has been exceeded, or even, in all the elements of the perfect 'sea-boat,' as adapted for these southern regions, proverbial turbulent seas and boisterous weather, been equalled." (Pages 125-6-7.)

The next extract shall consist of certain suggestions by Dr. Scoresby upon

THE IMPROVEMENT OF THE ADMIRALTY STANDARD COMPASS.

"Two improvements in the Admiralty standard compass, for its better adaptation to delicate observations or deviations, and for determining the true magnetic bearings of distant objects, were suggested by these and other observations made at Port Philip. The first was the adaptation of a much lighter card for being used under circumstances of great stillness and weak horizontal directive force. Before I was aware of the defective traversing of the lightest of the two cards usually supplied, though placed on one of the finest points, I was annoyed by finding differences in observations repeated, and in all respects similar or analogous, sometimes amounting to 1½° or 2°, and in two or three instances of still more. Such differences, indeed, I might have been prepared to expect in a new ship recently launched, and when being swung in different directions, especially under the vibration from hawsers employed in heaving round; but in our case there were no such influences in operation. On tapping the compass-bowl with the butt-end of a lead pencil, the discrepancies were sufficiently explained by observing frequently an immediate change in the direction of the card. This precaution, therefore, was subsequently adopted on each observation.

Another improvement, as it occurred to me, in a fine instrument designed to be employed as a steering, azimuth, or 'swinging' compass, would be the adaptation of a small telescope, adjusted to the circularly-moving rim, for giving assistance in observations of objects or positions on shore, when, as in the case of our reciprocal bearing, the place of the shore instruments could not be seen through the sights. Such telescope, too, would be of the greatest use when, as I repeatedly found, the shore object (its point, bluff, or other recognizable place) could only be indistinctly seen. In many cases whilst pursuing my observations in Hobson's Bay, the Saddle on the Dandelion, or the termination of the Red Bluff, could not be seen without the help of a glass (I usually employed an opera-glass), leaving the bearing by the sights to be made out by various shifts, such as the incidental proximity of some more visible point or object—a boat passing, a rope on board the ship, &c., for getting the bearing required. An attached telescope would have relieved me from all these embarrassments and risks of inaccuracy. It might possibly be applied to one or other of the shifting rims at present adopted; but in any convenient form it would be a valuable addition to the instrument." (Pages 179-80.)

The next quotation may consist of the following remarks on the fouling of the Royal Charter's bottom, and Dr. Scoresby's proposal for remedying the evil:—

THE FOULING AND CLEANSING OF IRON SHIPS' BOTTOMS.

"Though the ship had made capital progress for the fluctuating strength of the wind, we could not but remark that her sailing in light and moderate breezes was, for a ship of her build, rather heavy. This was ascribed to a disadvantage not hitherto overcome in iron ships—the rapid and extensive fouling of their bottoms by the adhesion and growth of weeds, barnacles, &c., which necessarily produce a deteriorating effect on a ship's sailing qualities. Various contrivances in paint and chemical colouring have been resorted to for the overcoming of this evil, but hitherto without much success. Nor has any process yet been devised for the clearing away of the fouling attachments without the costly and often impracticable operation of docking the ship. It has occurred to me, however, that much of the disadvantage might be overcome by a process of scraping, with no very complex arrangements for the guidance of the apparatus by means of a framework of changeable curvature guided by the keel; and an essential element in such arrangement, it seems to me, would be the attachment to the scraping apparatus designed for the bottom of the ship of buoyant or water tight air vessels, by which any degree of upward pressure on the scraper might be given. To the details of such an apparatus—which might be moved by rope forward and aft, as well as at right angles with the longitudinal motion by similar means—my attention has not been directed, nor might my habits of contrivance at all compete with the ingenuity and invention of practical and ingenious engineers or artisans." (Page 262.)

Our last extracts shall be on

MR. SMALL'S INSTRUMENT FOR DETERMINING COMPASS ERRORS.

"Among the magnetical and compass observations made in the course of the day, I made farther trial (having before had the instrument in action) of an ingenious patented invention of Mr. Andrew Small, maker and adjuster of compasses, of Glasgow, for finding by direct observation the true meridian, and consequently "the errors in deviation and variation of the mariner's compass." The instrument consists of an attachment to a compass on the ordinary principle of certain moveable circles in brass—a true meridian circle, an hour circle, and an equatorial circle, on the adjustment of which, in reference to the latitude, declination of the sun and apparent time, proximately, a stream of light from the sun's rays passing through a slit in the moveable hour circle is made, by the swinging of the interior

framework of the apparatus, to fall on the middle of the interior of the opposite side of the same circle (or to be put into position by using the slit as sight vanes), by which the meridional circle takes the position of the true north and south. The difference betwixt this and the direction of the compass-needle gives, of course, the errors of the compass observed with, in whatever position it may happen to be placed, and by comparison with the steering or other compass determines also its errors. My object being simply to test by experiment the performance of the instrument, to this object I confined myself, by a series of trials carried on from about 2 to 3 p.m., and frequently repeated. The deviation of which combined with the variation I had ascertained to be 7° westerly, and appeared to agree very well." (Pages 266-7.) "Repeated trials of the ingenious contrivance of Mr. A. Small, Glasgow, for determining by inspection the direction of the true meridian, and from thence the compass errors in deviation and variation, enabled me at length to form a decided estimate of its capabilities. The result was, that for moderate horary angles from noon the instrument acted well, pointing out the true meridian generally to within a degree or two, where the latitude and apparent time were pretty well known; but in the case of considerable intervals from noon, extending, as in our circumstances, to upwards of three hours from noon, the results become obviously erroneous to the extent, as at 7.30 a.m., of about 10 or 12 degrees to the westward of the truth, and at 5 p.m. to nearly as much to the eastward. This tendency to error in large hour angles I had suspected at an early period of my acquaintance with the instrument, on account of the results being obtained in dependence of a plane only proximately coinciding with the plane or cone of the sun's motion in the heavens. For observations, however, within moderate limits, the instrument appeared to work well, and readily gave the required information." (Pages 273-4.)

• INSTITUTION OF CIVIL ENGINEERS.

November 8th, 1859. Joseph Locke, Esq., M.P., President, in the chair.

The paper read was "ON THE PROCESS OF RAISING AND ON HANGING THE BELLS, IN THE CLOCK TOWER, at the New Palace, Westminster," by Mr. Jabez James, Assoc. Inst. C.E.

It was stated that the first large bell, which weighed upwards of 15 tons 18 cwt., and was cast by Messrs. Warner and Co., at Norton, near Stockton-on-Tees, was fractured while suspended from a staging at the base of the tower, during the course of experiments on the tone of the bell. The fracture took place on the opposite side from where the bell was struck by the clapper, which weighed 12 cwt. It passed from the lip through the sound-bow, and extended up the waist of the bell, and was about 40 inches in length from the lip. The fracture seemed to be clean, and the metal had a coarse dull appearance, and was full of minute holes, which were noticed in other parts of the bell when it was afterwards broken up. The four quarter bells were also cast by Messrs. Warner, but the third having been condemned as defective, had to be recast. The first, weighing rather more than 1 ton 1 cwt., was lifted in three hours; the second, weighing upwards of 1 ton 5 cwt., occupied three hours and a half; the third, which weighed above 1 ton 13½ cwt., took four hours. These three bells were raised by means of a single chain, made of bars 7-8ths of an inch diameter, and a crab with a double purchase. The fourth quarter bell, weighing more than 3 tons 17½ cwt., was lifted in six hours by a similar chain, reeved through a single pulley, and by a double purchase-crab. These bells were hung at the four angles of the tower, around the large

bell, for the convenience of sounding, &c. The second large bell weighed upwards of 13½ tons, and was cast by Messrs. Mears, at Whitechapel. The best method for raising this bell in a safe and economical manner having been carefully considered, it was decided to use a treble-purchase crab, with large blocks and a fall. A new chain, made by Messrs. Hawks, Crawshaw, & Co., 1,500 feet in length, and tested to a strain of 10 tons, was employed. This chain, when reeved through two three-sheave blocks, and with a standing chain, gave a power equal to about 70 tons. As the bell was 9 feet in diameter at the sound bow, and 7 feet 10½ inches in height, and the dimensions of the tower were only 8 feet 6 inches by 11 feet 1 inch, it was not possible to lift it by the crown, with the mouth downwards. Consequently, a cradle had to be constructed in which the bell should rest on its side. Friction rollers were attached to the cradle at the top and at the bottom, which served as guides, and rubbed against balks of timber set upright in the shaft. The upper block was made fast, by a shackle and clip, to a fitch beam formed of two plates of iron fixed between six timbers; and the lower block was firmly secured to the cradle by massive bolts and straps. The treble-purchase crab was fixed to a strong staging in the east-iron lantern at the top of the tower, in such a position as to leave a distance of about 19 feet between the bottom of the crab and the crown of the bell, when the latter was raised to its proper position. As the single barrel of the crab could not take up all the chain without incurring the risk of surging, consequent upon the coiling of the chain in so many thicknesses, several lifts were made, as stated in a tabular statement given in an appendix, in which was also recorded the time occupied for each lift, and the fleeting of the chain. An iron chain-stopper of special construction was made for the purpose of holding the chain during the fleeting on the drum of the crab. The weight of the bell and the cradle and iron work, together with the chain, blocks, &c., was about 25 tons, exclusive of friction. The process of raising commenced at six o'clock in the morning, and continued without intermission, until noon on the following day, when the bell was safely landed on a staging in the clock room. The cradle was then disconnected, and the bell was turned over with the crown upwards. An eye-bolt was passed through, and being now clear of the shaft, the bell was lifted in the usual way from the clock room to the bell chamber. The total height the bell was raised was 201 feet 3¼ inches, at an average velocity of about 6 feet 5 inches per hour. The paper then proceeded to state the experiments that had been made before the weight of the hammer and the distance it should fall through were finally settled. The weight was decided to be 6 cwt. 3 qrs. 10 lbs., with a fall of 13 inches. This arrangement for striking the hours was continued until the bell was discovered to be fractured in two places. One of the cracks was precisely in the same position in this bell as in the former one, exactly opposite to the place where it was struck by the hammer, and the other was about two feet away from it. The first fracture appeared to be about 15 inches and the second about 24 inches long; but they did not extend through the thickness of the metal, nor within 2 or 3 inches of the lip at present. The whole of the works for raising the bell were carried out by Mr. Hart, assistant to Mr. James, under the superintendence of Mr. Quarm, Clerk of the Works at the New Palace.

In the discussion, it was remarked, that the composition of the metal of the bell was not the same as that usually adopted in this country and on the Continent, there being a greater proportion of tin than was customary. It was also thought that the use of charcoal-smelted copper, as was the case in Russia, was advantageous. It was suggested whether the interval between the blows of the hammer might not have been too short, and whether the chattering of the hammer, due to its not being cleared immediately after striking, might not have a tendency to produce numbness, and hence stun the bell and contribute

to its fracture. It was urged that the great weight and fall given to the hammer must have acted prejudicially. These were supposed to be rendered necessary by the thickness of the metal, which had been made considerable, in order to guard against accident; but it was contended that it had a contrary tendency.

ROYAL GEOGRAPHICAL SOCIETY.

On Monday night, at one of the largest meetings, perhaps, ever held of the Royal Geographical Society, Captain M'Clintock, the distinguished Arctic navigator, read a memoir of his voyage on board the Fox in search of the survivors of the expedition of Sir John Franklin. The meeting, convened at half-past 8 o'clock, and at which Sir Roderick Murchison presided, was held in Burlington-house, Piccadilly.

Captain M'Clintock, who was cheered on presenting himself to the meeting, read his memoir of the incidents and results of his voyage, which, in point of fact, embodied the more interesting portions of his dispatches to the Admiralty published the day after his return to this country, and which are still so fresh in the public recollection as to render a repetition of them unnecessary. At its conclusion, however, he said there were two important questions which had been so frequently asked him that he gladly availed himself of that opportunity of offering some explanation upon so deeply interesting a subject. The first question was, whether some of the 105 survivors might not be living among the Esquimaux? The various families or communities of Esquimaux met with by Rae, Anderson, and himself, at different times and places, all agreed in saying, "No, they all died." The western shore of King William Island, along which they were compelled to travel for two-thirds of their route, was uninhabited, and all that was known of the mouth of the Back River was derived from the journeys of Back, Simpson, Anderson, and himself. None of them had met natives there, consequently it was fair to conclude that the Esquimaux but seldom resorted to so inhospitable a locality. In fact, their life was spent in a struggle for existence, and depended mainly upon their skill in taking seals during the long winter—a matter which required such long training that no European had ever yet succeeded in acquiring it. His (Captain M'Clintock's) two Greenland Esquimaux tried various methods at Bellot Strait, yet did not succeed; and without dogs trained to scent out the small breathing holes of the seals through the ice, and through the snow which overlays the ice and conceals them from observation, he did not think that even the Boothian Esquimaux could live. It required not only that a man should possess a trained dog, but that he himself should be so well trained in the only successful mode of seal hunting in this locality in order to subsist. It was therefore evidently an error to suppose that where an Esquimaux could live a civilized man could live there also. Esquimaux habits were so entirely different from those of other people that he believed there was no instance on record of either a white man or an Indian becoming domesticated among them or acquiring tolerable expertness in the management of a kayak. With regard to the probability of procuring the means of subsistence independently of the Esquimaux, he stated what was shot by his own sledge party—and they never lost a chance of shooting anything—during the journey along the lands in question, which occupied them for 79 days and covered nearly 1,000 geographical miles of distance. The sum total amounted to two reindeer, one hare, 17 willow grouse, and three gulls. The second question was, why had the remains of so few of our lost countrymen been found? It was indeed true that only three of the 105 were discovered, but it was to be borne in mind that from the time they left their ships they were dragging sledges and boats, and therefore they must have travelled almost constantly upon the ice—not upon the land—consequently all traces or remains there vanished with the summer thaw of 1848. There was no doubt that many relics still remained strewed along the

uninhabited shore of King William Island, beneath the snow; but as it was most carefully examined three times over, he could not think that any conspicuous object, such as would be put up to indicate where records were deposited, could possibly have escaped them. The summer at Port Kennedy proved a warm one, yet the ice did not permit them to move until the 9th of August, and the object of the expedition having been attained, they commenced their homeward voyage.

Sir Roderick Murchison said (among other things), to geographical science the results of Captain M'Clintock's expedition were little less than glorious, for, among others, it had determined for the first time the navigability of Bellot Strait, and the northernmost part of the American continent. In the forthcoming narrative (to be published shortly by Captain M'Clintock) the difficulties which those gallant men had surmounted would be presented to the world in detail. The very first incident of their voyage in a little yacht of only 170 tons was that when they had nearly reached Baffin-bay they were drifted back 1,200 geographical miles into the Atlantic again. But they returned to the charge, and eventually succeeded for the first time in revealing the fate of the illustrious Franklin and his associates. There was no doubt that Franklin went further to the north in a ship than any British seaman—he (Sir R. Murchison) was speaking of the search made in Wellington Channel,—and then he returned, and performed that extraordinary voyage round Cornwallis Island, by which, in the first year of his enterprise, he proved it to be an island.

An interesting discussion followed on the results of Captain M'Clintock's expedition, principally as determining the fate of Franklin, and also as it bore upon the progress of geographical discovery, in which several of the experienced explorers of the Arctic regions present took part, including Sir Edward Belcher, Captain Collinson, Captain Sherard Osborn, Captain Hobson, Captain Snow, and Captain Kennedy. Captain Collinson gave it as his opinion that after Franklin and his comrades abandoned the ships, it was almost impossible, having regard to the question of provisions, and to the probable rate at which they would be able to travel, encumbered as they were with sick, with boats, and facilities for prosecuting their journey, that they could have reached further than the bottom of the estuary of the Great Fish River, and that they all perished. Captain Sherard Osborn, as an Arctic navigator, said he could not resist the conclusion that the search for Franklin was now closed. He had read Captain M'Clintock's journal, which was written from day to day, without any wish to arrive at a particular theory, and therefore on that ground eminently valuable, and he felt that, whatever the track Franklin and his comrades took after abandoning the ships, it was their last journey upon earth, and that they must have perished. Captain Snow in an animated speech stated the reasons for believing it possible that some members of the Franklin expedition still survived, which he has already propounded in the public journals. He submitted that the evidence was not conclusive that they were all lost, and that it would be to the honour of England to make an attempt worthy of her honour to ascertain their fate. He pledged his word, if health were spared to him, and whether he was assisted or not, that he would depart next spring, with the view of going over the whole ground, and, if need were, would ally himself with the Esquimaux until the riddle was solved. Sir R. Murchison, in adjourning the meeting, said it was a great fact in which all those naval officers who had taken part in the discussion, whether belonging to Her Majesty's service or to the mercantile marine, agreed that, although Captain M'Clure was worthily rewarded for making a North-West passage, Franklin was the man who made the North-West passage.

A vote of thanks having been unanimously accorded to Captain M'Clintock for his memoir, the meeting separated at nearly 11 o'clock.

THE SOCIETY OF ARTS.

The first ordinary meeting of the 106th session of this society was held on Wednesday evening within their hall, John-street, Adelphi. The attendance was numerous. The chair was taken at 8 o'clock by Sir Thomas Phillips, F.G.S.

The Chairman, after numerous applications for admission to the membership of the society, and other routine business had been proceeded with by the secretary, rose, and after alluding to the time-honoured custom of the society, that the session should be opened by an address from the chairman of the council, acquainting members with the policy which the council designed to follow during the ensuing session, proceeded to notice the decease of several members, the election of Sir William Page Wood to a vice-presidentship left vacant by the death of Robert Stephenson, and the Exhibition of 1862. The progress of art and the organisation of local boards were next referred to in the address. It was also intimated that the Turner and Vernon collections of paintings at South Kensington would shortly be opened to the public during the evening. The present state of the law of copyright was next referred to, as well as another important matter which had been brought before the society under the presidency of Dr. Whell, and which had occupied much of the attention of the council—that it was desirable to establish a uniform musical pitch. It remains with the committee appointed to consider and report what pitch shall be adopted in this country. A large mass of correspondence has been collected during the vacation on the subject. The address concluded with showing the vast increase in commerce, arts, and manufactures that had taken place during a recent period.

Mr. Webster, who rose to move a cordial vote of thanks to the chairman for the address just delivered, expressed his fullest confidence that the announcement of the determination of the council to organise an industrial exhibition in 1862 would be sympathised with throughout the country. He felt confident that through the progress of art and science a quinquennial exhibition might now be proceeded with, independent of the position of foreign affairs. He urged the importance of co-operation, and, in conclusion, drew attention to the present state of the law of copyright and of trade marks.

Sir W. Page Wood rose to second the motion, and return thanks for himself personally for the honour conferred on him by his nomination to fill the office so recently vacated by the lamented death of Robert Stephenson.

Several members next joined in a discussion relative to securing other premises, when, after the presentation of medals to various persons, the meeting was adjourned until next Wednesday, when Sir John Bowring will read a paper on the arts and manufactures of China.

MEETING FOR THE ENSUING WEEK.

TUESDAY.—Inst. Civil Engineers, Discussion "On the Government Water-Works, Trafalgar Square," and, if time permits, a paper "On Arterial Drainage and Outfalls," by R. B. Grantham, Esq., M. Inst. C.E., at 8 p.m.

Law Cases.

MIDWORTH'S PATENT BEATERS.

VICE-CHANCELLOR'S COURT, NOV. 16.—(Before Vice-Chancellor Sir W. P. Wood.)

GOUCHEE v. MIDWORTH.

This was a motion for an injunction to restrain the defendant from manufacturing and selling thrashing machines with grooves or channels in the surface of the beater, in imitation of the plaintiff's patented thrashing machine, and generally from infringing his patent, which was taken out in November, 1848. The case set up by the defendants was that there was no novelty in the plaintiff's patented invention, which was in effect a mere colourable imitation of an older patent taken out by one Dry in 1842, now expired, and of which there were several modifications in con-

stant use. The defendants also denied any infringement of the plaintiff's patent in the machines sold by them, and contended that upon their evidence the enjoyment by the plaintiff had not been so uninterrupted as to entitle him to an injunction before bringing his action, although his right to an account was not denied.

Sir Hugh Cairns and Mr. Jessel appeared in support of the motion; Mr. H. F. Bristowe opposed the motion on behalf of the defendants.

The Vice-Chancellor, after observing that even where there might be considerable doubt as to the validity of the patent, still where there had been long and undisputed enjoyment the Court would grant an injunction, though upon terms to be imposed on the plaintiff, said that the statement of the defendant as to the want of novelty in the plaintiff's invention, which had been patented as long ago as 1848, was entirely unsupported. If ever there was a case of clear and undisputed possession and enjoyment it was this. Until the matter had been actually tried at law he could not, of course, say that there might not be a case to be tried. Then as to Dry's patent, looking at the specification, anything more unlike it than the plaintiff's patent could not be suggested. At present he was very far from feeling that it was a case of strong doubt, as had been suggested by the defendants, and the injunction must be granted, the plaintiff undertaking to bring an action and abide by any order as to damages.

COAL-BURNING LOCOMOTIVES.

COURT OF QUEEN'S BENCH, NOV. 16.—(Sittings in Banco, before Lord Chief Justice Cockburn and Justices Hill and Blackburn.)

THE MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY COMPANY v. WOOD.

This was an appeal from a conviction by the magistrates of Sheffield, whereby they had convicted the Manchester, Sheffield, and Lincolnshire Railway Company of using upon their line a locomotive engine which was not "constructed upon the principle of consuming and so as to consume its own smoke." The case stated that the engine No. 37 was seen emitting black smoke for four minutes at the Sheffield Railway station, at 4 o'clock in the morning, and afterwards, when it moved along the line, it was again seen for four minutes emitting black smoke. The company, when summoned before the magistrates contended that the engine in question was constructed on the best known principle for consuming its own smoke; but the magistrates without entering into this question considered that the fact that the engine emitted black smoke was conclusive that it was not "constructed on the principle of consuming and so as to consume its own smoke," as required by the 114th section of the 8th Victoria, cap. 20, and fined the company £5.

Mr. Quain, for the respondents, contended that the magistrates were right.

Mr. Mellish, for the appellants, contended that the magistrates ought to have gone into an inquiry as to whether or not the engine in question was constructed on the principle of consuming and so as to consume its own smoke. It might have been that the only cause of the engine's smoking was the negligence of the engine-man.

Lord Chief Justice Cockburn said the Act did not say that the company should be liable to a penalty if their engines emitted smoke; and this Court could not go beyond the Act of Parliament. The fact that the engine emitted smoke would be strong evidence that the engine was not "constructed on the principle of consuming and so as to consume its own smoke;" but it was not conclusive. The case must go back to the magistrates to inquire whether or not the smoke arose from the defective construction of the engine. If the Legislature had intended to say that the company should be liable to a penalty, under all circumstances, where an engine emitted smoke, it would have used a more stringent enactment.

Mr. Justice Hill and Mr. Justice Blackburn were of the same opinion.—Case remitted accordingly.

THEORY OF NAVAL ARCHITECTURE.

No. X.

In the construction of ships there are, as we have already stated, two planes which may be made use of as the horizontal plane of projection; the first, that of the load water line, and the other a horizontal plane through the upper edge of the rabbet of the keel. When the plane of the load water section is taken as the horizontal plane of projection, the transverse sections being drawn perpendicular to it, the same method of calculation as that given in our first example must be followed for obtaining that portion of the displacement bounded by the extreme, horizontal and transverse vertical sections; but since in ships which draw more water abaft than forward the plane of the load water section is not parallel to the rabbet of the keel, the lowest section cannot be made to inclose the entire displacement exclusive of the keel; there will, therefore, be an appendage between the lowest section and the bottom of the keel similar to that represented in Fig. 19, included between $5\frac{1}{2}$ W. L. and the lower part of keel. Besides this the rudder and posts abaft the aftermost section must be taken when the ship is built of wood; also where the stem curves inwardly at the foot, a portion situated before the foremost section at the upper part must be added, and as its lower part is inside the extreme sections, and not terminated by them, the space between the stem and the extreme sections is assumed to be of the same thickness as the stem when measuring off the ordinates, and the portion thus taken in excess is afterwards subtracted from the result first obtained.

Our former example and the above observations will, therefore, be sufficient to explain the method of performing the calculations in any case where the plane of the load water line is taken as the horizontal plane of projection.

The adoption of the plane of the load water section as the horizontal plane of projection is obviously the most simple for making the ordinary calculations, but it is open to the following objection:—When the building draught has to be made it is necessary to take the horizontal plane through the upper edge of the rabbet of the keel as the plane of projection, consequently there is a large amount of labour necessary to shift the planes of projection in addition to the operation of taking off the planking; constructors, therefore, who have little time to spare, first complete their building draught, and afterwards put on the planking, for the purposes of calculation retaining the same planes of projection. It is evident, therefore, that the curves drawn in the half-breadth plan are the projections of the several horizontal sections of the ship on a plane inclined to their planes; and further that transverse sections drawn perpendicular to the load water section would not be represented, in the half-breadth plan, by straight lines perpendicular to the middle line, but by curves, in obtaining which much time would be expended. The projections of the horizontal sections are, however, made use of for the purposes of calculation, and, as we shall prove, the displacement so found is essentially correct.

We shall, therefore, assume that the planes of projection are those generally made use of for the building draughts, and that the curves in the half-breadth represent the projections of the horizontal sections of the ship at the outside of the planking. And by way of example we will perform the calculations for a ship of war of the following dimensions:—

Length between the perpendiculars ..	180' 0"
" of the keel for tonnage	160' 7 $\frac{1}{2}$ "
Breadth, extreme	28' 4"
" for tonnage	28' 0"
" moulded	27' 6"
Depth in the hold	16' 0"
Burthen in tons No.	670
Draught of water { Forward	12 feet.
{ Aft	14 "

Our object now will be to obtain the areas of the curvilinear figures on the half-breadth plan. For this purpose the foremost and aftermost sec-

Distance between the Vertical Sections 9'4 feet; Ditto between the Horizontal Sections 2'65 feet.

FIG. 19.

tions or ordinates are placed at the rabbets of the stem and post, as before explained; and the distance between them, measured on the middle line of the half-breadth plan, is divided into a number of equal portions suitable for the application of the rules given for obtaining curvilinear areas, and at the points of division lines are drawn perpendicular to the middle line. These lines represent transverse sections perpendicular to the upper edge of the rabbet of the keel, and in Fig. 19 are represented by the vertical sections 1, 1½, 2, &c. The ordinates are then measured off from the half-breadth plan, and inserted in the table, as already described in our former example, and the calculations proceeded with as though the transverse sections were perpendicular to the load water sections.

In our present example, the distance between the extreme vertical sections measured on the middle line is divided into 18 equal portions, each being 9¼ feet; and for greater accuracy, the two extreme intervals are again divided into two equal portions respectively, as is shown in the Fig. 19.

In placing the horizontal sections they are so arranged that the third rule for approximating the curvilinear areas may be applied. There are at the upper portion of the displacement four equidistant sections, and at the lower portion four other equidistant sections. The common distance between the sections L. W. L. and 2 W. L.; 2 W. L. and 3 W. L.; 3 W. L. and 4 W. L., is 2.65 feet, measured on the sections drawn perpendicular to the rabbet of the keel, and the common distance between the sections 4 W. L. and 4½ W. L.; 4½ W. L. and 5 W. L.; 5 W. L. and 5½ W. L. is $\frac{2.65}{2}$ feet, measured on the same sections.

Performing the calculations in the same manner as described in the former example, we obtain first the areas of the projections of the several horizontal sections; and before being multiplied by $\frac{1}{3}$ rd of the common interval they are to be found in the first horizontal column below the ordinates; they are 32.75, 93.75, 194.75, 297.5, 452.8, 550.95, and 621.4. Suppose we have multiplied these results respectively by one-third of the common interval, and so obtained the areas of the projections of the several horizontal sections, these areas will be equal to the true areas of the respective sections, multiplied by the fraction $\frac{1}{L}$, L being

the distance between any two vertical sections, measured on a horizontal section, and l the distance between them measured on the middle line of the half-breadth plan; the true area of any horizontal section may therefore be readily found from these areas given in our table. Generally, however, the fraction $\frac{l}{L}$ is so near unity that the

areas found in the table may be taken as the true areas of the sections, without any practical error; and it is only in cases in which the difference of draught of water forward and aft is very considerable in proportion to the length of the ship, that

the multiplication by the fraction will be necessary.

Let us assume, however, that we have obtained the true areas of the horizontal sections, and let them be respectively represented by $A_1, A_2, A_3, A_4, A_5,$ and A_6 .

To obtain the displacement from these we have only to multiply them respectively by 2, 6, 6, 3, 3, 3, and 1, in accordance with the third rule for finding a curvilinear area, and their sum multiplied by $\frac{1}{3}$ ths of the perpendicular distance between the sections, will give the displacement. Now, the perpendicular distance between any two sections is equal to the distance between them, measured on a vertical section, multiplied by the fraction $\frac{l}{L}$: it is obvious, therefore, that if we

make use of the projections of the areas of the horizontal sections (which are the true areas multiplied by the fraction $\frac{l}{L}$) and take the distances between the horizontal sections, as measured on a vertical section, we shall obtain the correct displacement.

To obtain the displacement by *transverse sections*, the rationale of the operations will be readily made out. For, since the common interval between the horizontal sections is measured along the transverse sections in the sheer plan, when the ordinates for any section are put into the rule, and the sum multiplied by the proper fraction of the common interval, the result will be the true area of that section. And since the common interval between the transverse sections is the perpendicular distance between any two consecutive ones; when their areas are put into the rule, and the sum multiplied by the usual fraction of the common interval, the result will evidently be the displacement.

Another explanation may be given of the manner of finding the displacement inclosed by the extreme sections from the projections of the outside of the planking, as delineated on the *building draught*. Taking, as before, the extreme transverse sections at the outside of the rabbet of the stem and stern-post at the load water line, let the distance between them be measured on the L. W. L. in the sheer plan, and then divided into the same number of equal parts as was the distance between them on the middle line of the half-breadth plan, and through the points of division let transverse sections be drawn perpendicular to the upper edge of the rabbet of the keel; these sections will, of course, coincide with those before drawn, but since the common interval is measured on the horizontal sections, the true areas of the horizontal sections will be found on the table, and not their projections as before. Again, the common interval between the horizontal sections must now be measured perpendicularly to them, and not along the transverse sections, as in the former case; it is easy to see, therefore, that the true displacement will in the end be arrived at by the *horizontal sections*.

To proceed with the transverse sections we shall

first have their projections on a plane perpendicular to the load water line, and not their true areas, but as before the true displacement will be obtained when these are put into the rule, and the common interval taken as measured along the horizontal sections.

With these observations, we shall leave the student to work out the example for himself, as no difficulty can present itself respecting that portion of the displacement which is inclosed by the extreme sections; the work is precisely the same as in our former example.

The small portions of the displacement situated outside of the extreme sections are found by the ordinary rules of mensuration, as also are their centres of gravity, and the necessary corrections are made in the results before obtained.

In the present example the portion below 5½ W. L. contains 167 cubic feet, and its centre of gravity, situated at b , Fig. 19, is 120 feet from section 1, and 12.5 feet from the L. W. L.

The contents of the rudder and stern posts abaft the section 19 are 65 cubic feet, and the centre of gravity situated at c , Fig. 19, is 180 feet abaft section 1, and 6.25 feet below L. W. L.

The portion between the stem and the extreme sections, which must be subtracted, contains 22.8 cubic feet, and its centre of gravity, situated at a , Fig. 19, is 2.5 feet abaft section 1, and 9.5 feet below L. W. L.

The positive portions amount to 167 + 65, or 232 cubic feet. The negative portion is 22.8; the total positive appendage is therefore 209.2 cubic feet, which must be added to 28198.2757, the displacement situated between the extreme sections, to obtain the total displacement. In forming the scale of displacement, the proper appendages must also be taken into the calculations.

Again, in obtaining the centre of buoyancy in our former example, there were no appendages to the displacement. In the present case, the centre of buoyancy corresponding to the portion inclosed by the extreme sections is found as in that example, and it then remains to find the effect of the appendages upon its position in a vertical and also in a horizontal direction. This may be readily done by means of the property of the centre of gravity proved in our last article, page 215. Assume that the axes ox, oy both pass through the centre of gravity, above found, of the displacement inclosed by the extreme sections, and that they are parallel to L. W. L. and section 1, then we have only to find the moments of the appendages about ox and oy .

On reference to the table it will be found that the centre of buoyancy without the appendages is 4.3115 feet from the L. W. L. and 86.69 feet from section 1; consequently the centre of gravity of the keel piece is 12.5—4.3115, or 8.1885 feet from the L. W. L.; therefore $167 \times 8.1885 = 1367.5$ is the product of its weight and distance from ox , also $6.25—4.3115 = 1.9385$ is the distance of the centre of gravity of the rudder and posts from ox ; and $9.5—4.3115 = 5.1885$ is the distance of the negative portion forward from the same axis,

CAPTAIN COLES' PATENT SHIELDS FOR ORDNANCE.

therefore $65 \times 1.9385 = 126.0$, and $22.8 \times 5.1885 = 118.3$; the sum of the positive products is 1493.5, and the negative product 118.3, the result will therefore be positive, and equal to 1375.2. This quantity divided by 28407, the total displacement in cubic feet, including appendages, will give .0485 feet for the distance of the centre of buoyancy below that corresponding to the displacement between the extreme sections, or the centre of buoyancy below L. W. L. is 4.86 feet. In a similar manner, the distance that the centre of buoyancy moves aft by the addition of the appendages may be found to be .34 feet, as given in the table. The centre of buoyancy is therefore 87.03 feet abaft section 1, when the appendages are taken into account.

The student will now, we think, be able to make the ordinary calculations for any ship, with either of the usual horizontal planes for the plane of projection, and in the above example he will complete for himself the drawing containing the scale of displacement, the scale of the area of the midship section, and that of the tons per such immersion similar to those given on page 298, vol. I., for our first example.

MONSTER TROOP STEAMER.—The following paragraph has been communicated:—Messrs. Pearse and Co., Stockton, have on the stocks for the Government an Indian river steamer of immense proportions. Her length in the water-line is 350 feet, over all 375, and breadth 46 feet. She is by far the largest river steamer in the world. Her engines are 200 horse power. She will be impelled by paddles, and will, it is expected, attain a speed of 13 miles an hour. She will be fitted with sleeping berths and every suitable sanitary arrangement for about 800 soldiers. She will be guided by two large patent steering blades, and is made to draw only two feet of water, even with all her stores, fuel, and 800 passengers on board. She is flat-bottomed of course, and weighs about 370 tons. She will be completed in about a month, and will then be fitted up on the Thames, in order to make an experimental trip.

CAPTAIN COLES' PATENT SHIELDS FOR ORDNANCE.

CAPTAIN COWPER PHIPPS COLES, R.N., has recently patented an apparatus for defending guns and gunners in ships of war, gunboats, and land batteries. His invention consists of a large convex shield covered all over its exposed portion with thick iron or other metal, and mounted upon a platform or frame which is capable of revolving after the manner of a turntable, and which also carries the gun upon any suitable carriage. An aperture is formed in the shield to allow the muzzle of the gun to pass through it, and this aperture is somewhat larger vertically than horizontally in order to admit of the elevation and depression of the gun, the lateral aim being secured by the rotation of the platform. Captain Coles does not limit himself to any precise form or mode of construction, but he usually prefers to make the shield hemi-spherical, and to construct it of a wooden frame with timbers in vertical planes placed close together, the whole being covered with thick iron plates. In the engravings hereto annexed, we have illustrated the manner in which he carries his invention into effect. The figure is a transverse section of a shield, constructed according to his invention, and adapted to a land fort or battery. The body of the shield is composed of a compact framing of timber *A*, the whole exposed upper portion of which is covered with thick iron plates *B*. The shield is built upon a revolving timber platform or frame *C*, which turns about a central bolt or stud *D*, and runs upon conical rollers *E*, placed beneath it near its circumference. These rollers are carried by arms *F*, which are attached to a loose running central ring *G*. The conical rollers *E* run upon a metallic rail or tram, supported by a floor or platform *H*. The rotary motion which is requisite in the training of the gun is obtained by means of a hand-wheel *I*, fitted within the shield and connected with gearing, which works a pinion *K*, that travels round in teeth or cogs formed upon the circumference of the metallic rail or tram. *L* is the aperture through which the gun protrudes.

The aperture *L* is only sufficiently wide to allow the muzzle of the gun to pass through it, but is of sufficient size vertically to allow of the depression and elevation of the piece. A narrow aperture *l* is continued up from the main aperture *L*, to admit of the gunner "sighting" the gun with ease and accuracy. When the shield is formed and fitted as shown in the engraving, the ammunition must be supplied through an aperture made for the purpose in the rear of the shield. But in some cases, as on board ship for example, Captain Coles prefers to employ a hollow cylindrical casing in place of the solid central bolt or stud *D*, and pass the ammunition up from below through it. In like manner he proposes in other cases to modify other details of the apparatus. Instead of making the shield of an arched or curved form, for instance, he makes it polygonal in horizontal section, and straight-sided in vertical section, or of any other prismatic or other form, which will present a convex or inclined surface throughout to shot and shell. He likewise sometimes mounts the shield upon spherical balls, or rollers, or otherwise, instead of upon the conical rollers before described, and in place of the hand wheel and gearing for rotating it, he employs any other suitable appliances for the purpose. Further, he provides for the escape of smoke from the shield, and for its ventilation, by forming apertures in it for the purpose, and sometimes (as where a central upward passage is provided for the ammunition) by forcing air continually through the shield by means of a fan placed beneath it. Finally, he proposes to form the shield large enough in some cases to cover two or even more than two guns side by side and parallel to each other. When the shield is employed on board ship it should be either built or placed somewhat eccentrically in order that the common centre of gravity of the shield and the gun or guns beneath it may be caused to fall in the centre, about which the whole rotates. This will prevent the same from having any disposition to rotate imparted to it by gravity as the ship rolls or pitches. Captain Coles prefers to mount the guns placed beneath the shield upon

carriages resembling that invented by Mr. Marshall in 1827, but modified to suit the purpose more effectually. We have no account of the manner in which this modification of the carriage is to be effected, and have consequently had engraved within the shield a gun and carriage taken from Commander Marshall's original description of 1827. The following account of this part of the engraving is derived from the same source. "A is the breech carriage,* which differs only from the ordinary carriage in its shape before, which will be understood sufficiently by the drawing; B is the coin; C is the trunnion, and D the asp over the trunnion; E is the muzzle carriage, having its wheel or wheels F, in this position at right angles with the wheels of the breech carriage; F is a mere solid block of wood; G, H are two plates bolted to it with eyes at one end *r* and *t*, to receive the hinged bolt J; this bolt passes through another eye *s*, which is bolted to the ship's sides and steps into a socket made for it in the water ways; K represents the ship's side, and L the water ways, and *n* the socket; N is a strong iron crutch, with a piece of hard wood *i*, fitted in the middle of it for the muzzle of the gun to traverse upon; this crutch turns on the central bolt or pivot P, which is set into a socket made for it in the block or bed of the muzzle carriage K; the gun is here supposed to be run out in a straight direction for firing, and if it were fired the recoil would cause the gun to run in the muzzle, and traversing on the wood *i*, till the crutch came to the muzzle rim, or beyond it if required according to the lengths of the ropes or breechings. By this arrangement a hand spike or tackle applied to the muzzle carriage at X, on either side, will point the gun with the greatest nicety and facility, the wheel or wheels F being, as will be observed, in the proper position for that movement." It should be observed that the characteristic feature of Commander Marshall's carriage consisted in mounting the breech and muzzle of a gun on two separate carriages, one supporting the breech and the other the muzzle, and the wheels of one being at an angle with those of the other.

DOUBLE CYLINDER EXPANSION MARINE ENGINES.

At last year's meeting of the British Association, Mr. John Elder, Engineer, of Glasgow, gave a description, with plans, of the various double cylinder expansion marine engines for ocean steamships that had been constructed by his firm during the last six years. At the late Aberdeen meeting he added those of the Callao, Lima, and Bogota, together with those of some others now in progress. Before entering on this subject he reminded the Association that these engines are constructed with the view of getting the greatest amount of power from a given quantity of steam, at a given pressure, with less total weight of engine-boilers and water, and occupying less total space than that occupied by the ordinary class of steam-engines on board of steam-ships. At the former meeting he had mentioned that the above steam-ships, with the ordinary first-class system of machinery, were coming from Valparaiso to this country to have their engines replaced by these double-cylinder engines, entirely for the purpose of saving of fuel—the Lima and Bogota. They are of the following dimensions:—Length, 245 feet; breadth, 36 feet; depth, 23 feet; breadth between paddle-boxes, 86 feet; tonnage, 1,650 tons. These ships had formerly a full poop and fore-castle, which were altered this year into a spar deck, and the hulls of the ship increased in weight about 120 tons; the cabin and hold accommodation was lengthened 30 feet by the space saved by the smaller quantity of coal and boiler space required for the new machinery; and the registered tonnage of the ship was increased by upwards of 400 tons. The following statements are in the language of Mr. Elder.

In the engines of the Lima, Callao, and Bogota,

* We here preserve Mr. Marshall's language, but without reproducing the letters of reference in the engraving.

the cylinder capacity is so great as to admit of the steam being expanded to within two pounds of the pressure in the condenser at the end of the stroke, while the engines are working full power; and as the nominal power of these engines is contracted to be 320, the cylinders are 90 in. diameter, and 5 feet stroke; and, in order to reduce the violent shock of high-pressure steam on such a large piston, and also to increase the jacket surfaces, a cylinder of one-third the size, or 25 in. diameter, and 5 feet stroke, is placed close to it. This small cylinder receives the steam direct from the boiler during one-third of its stroke; this steam is consequently reduced to one-third of its original pressure at the end of its stroke, and then enters the second cylinder, where it is expanded three times more, making a total of nine volumes. Thus 42 lbs. steam is expanded nine times, or to 14 lbs., namely, from 42 lbs. to 14 lbs. in the small cylinder; it then enters the large cylinder at 14 lbs., and is expanded to 4 lbs., but as the second piston is three times the size of the first, the gross load will be the same on both pistons, and the piston rods, crossheads, and connecting rods may be duplicates of each other.

From the above pressures of steam at the entering of the cylinder, it is evident, that unless the inside surface of the large cylinder is retained about 210 degrees, condensation of the steam on entering is certain, and such condensation will chiefly evaporate into the condenser while the eduction port is open, and the latent heat necessary to evaporate such condensation will be much greater than what would have radiated from the hot cylinder to the condenser, had no condensation taken place; and such heat would be entirely lost. In the same manner it might be mentioned, that the inside surface of the small cylinder should be retained as high in temperature as the steam that enters it; and in order to attain this object every effort should be made in the construction of steam machinery. It is evident that, for the small cylinder, superheated steam is absolutely necessary for this purpose, either in the jacket or cisterns of the cylinder; and in the large cylinder the temperature of steam direct from the boiler to the cylinder may be sufficient, if communicated through a large enough pipe or aperture.

In the engines under description the pipe supplying steam to the jackets was 2½ in. diameter, and the steam was superheated to upwards of 400 degrees that entered the jacket. It was found that a large supply to the jacket saved a vast quantity of heat, which can only be explained by the principles above mentioned, namely, that any quantity of heat supplied to the jackets assisted in proportion to the quantity of latent heat it saved being evaporated to the condenser during the eduction of the steam, and if the pipes to the jackets were large enough, or sufficient to prevent the condensation referred to, the economy of the machinery was realized to the greatest extent.

Mr. Elder called the attention of all parties concerned to the performance of Cornish pumping engines, and more particularly to the similarity of action of the steam jacket in these engines to the principle of that of the double cylinder engine with steam jackets. In the Cornish engine the piston it is single acting, and the jacket has twice the time to do its work, or rather the steam in the cylinder is twice the time in contact with the jackets that it is generally with Watt's engine, also that the Cornish engines have very large jacket surfaces in proportion to the power developed. With these features in view, the engineers constructed the engines now under discussion, and to this cause may be attributed a considerable portion of their success, and to the non-observance of these features the almost total failure of economy in the expansive working of most steam engines on board of steamships, namely, by constructing large engines, going slow, without steam jackets, or superheating of steam; such engines would, of course, present a most favourable opportunity for improvement by adding any mode of superheating apparatus.

In the Cunard line, and many of our ocean steamers where very high steam chests and large

hot uptakes pass up through the steam, the economy of expansion has never been questioned, but can be substantiated to a considerable extent at any time. It is likely, however, that were the temperature of the steam from such boilers ascertained, it would be found considerably superheated. And the use of the various modes of superheating has been rendered much more necessary than it otherwise would have been, by engineers generally following that type of tubular boiler used by the Admiralty where there are low steam chests, and short uptakes, said to be rendered necessary in the case of the Admiralty on account of exposure to shot.

From the foregoing it is also conclusive that with the ordinary construction of steam-engines afloat, that small engines going fast would consume less coal per indicated horse-power than large engines going slow; but with engines such as those of the Callao, Bogota, and Lima the converse will be the case, carried, of course, to within moderate limits.

Again, to return to the case of the Callao, Lima, and Bogota, the general construction of the engines and boilers are as follows:—The cylinders are four in number, namely, two of 53 inches diameter, and two of 90 inches diameter and 5 feet stroke. The cylinders lie diagonally to each other. The steam and eduction valves are wrought with eccentrics, the steam valve is a gridiron valve with a large lap; one eduction valve serves as eduction for the high and its corresponding low-pressure cylinder; it has no lap, and the eduction port remains open during the entire stroke of the piston, thereby giving a free escape for the steam, and ample escape for water should it form.

In reversing the engines the eccentrics are made to overrun the engines by a donkey-engine till they arrive at the backing position—a plan which is less likely to cause accident than the ordinary methods. This donkey-engine has been found to be most satisfactory in its application.

The boilers are tubular, two in number, with iron tubes. Each boiler has three furnaces, 3 feet 4 inches wide, and 6½ feet long, or making an aggregate of 130 square feet of fire-grate. The tubes are of iron, 288 in number, 4 inches inside diameter, and 6½ feet long. Each vessel has an oval steam chest, 12 feet high, and 8 feet long, and 5 feet broad, with three uptakes through this steam chest each 2 feet diameter and 15 feet long. This makes a strong form of take-up where it joins the tube plate, especially in boilers firing across the ship; the feed-pipe of the boilers enters into a long flat tank or shield in front of the furnaces in which the furnace-doors are formed. This shield forms a protection to the firemen from heat, and makes the heat, otherwise lost, available for the feed-water. In the Callao there is a third coil of feed-pipe in the funnel, to heat the feed-water. Such, then, are the leading features of this machinery, and the results are as follows:—

This plan of the boilers gave steam to the engines superheated to about 400 degrees by the uptakes, showing that the various systems of superheating are unnecessarily complicated; indeed, in the Lima, the steam got so far above 400 degrees, that in the Bogota the steam chests were made two feet lower, and two small feed-pipes were made to feed the boiler when too much superheated by the tap of the steam chest. The superheated steam, though upwards of 400 degrees of heat, was found quite inadequate to prevent condensation in the cylinder, without the steam-jacket cock being full open.

Mr. Elder pressed this fact on notice, as in the case of double-cylinder engines it is so prominently observed, by comparing the respective diagrams of the low and high-pressure cylinders, especially as those engines, where the cylinders are so close that the diagram of one is an exact counterpart of the other, when there is no condensation; and it is somewhat curious to observe, while taking diagrams of the low pressure cylinder, the gradual development of the diagram, with the jacket-cock full open, compared with that when it is shut.

When the steam was at a pressure of 21 pounds above the atmosphere the temperature at the surface of the water was 264 degs., and at the top of the steam chest 400 degs. Fahr., showing that the steam was surcharged to the extent of 136 degs., notwithstanding that the steam was in direct and unimpeded contact with the surface of the water. The engines made during the trial trips, which were generally half-a-day in length, from about 23 to 26 revolutions, and indicated from 1,000 to 1,300 horse-power during that time, and consumed from 20 to 25 cwts. per hour, with the surface blow-off cocks open. The Callao, Lima, and Bogota have all shown a consumption of from 2 to 2½ pounds per indicated horse-power per hour best Welsh coals, and the speed of the ships from 12½ to 13 knots per hour.

The steam-ship Callao has now been plying between Valparaiso and Panama with Her Majesty's mails for upwards of nine months, and has performed her work in a most satisfactory manner. The distance between these is upwards of 3,200 miles, and this she performs regularly on about 300 tons of coals. The Callao made the run from Liverpool to Valparaiso in, I think, about 36 days steaming time, which averages about 240 miles per day during a run of 9,000 miles on a consumption of about 20 cwts. per hour. The Lima has also arrived at her destination after a most successful run; she performed the distance of 1,500 miles, from Valparaiso to Callao, in 141 hours, consuming 150 tons of coals, logging at an average of 260 miles per day during that distance, considerably faster than she had ever done with her original engines, and on less than half the coals consumed. The Bogota was completed and tested on the first of September last, and found fully equal to the others. She made the run from the Cloch Light in the Clyde to the Hell Buoy at Liverpool in 15 hours, against a strong head wind, and consumed during that distance 15 tons of Scotch coals.

At the Admiralty trial, which took place immediately on her arrival at Liverpool, she averaged upwards of 13 knots, the engine made 25½ revolutions; she indicated 1,080 horse-power, and consumed about 21 cwts. per hour of Scotch coals; the steam was superheated to 340 degrees on entering the cylinder, and the thermometer at the water level of the boiler showed 264; the pressure in the boilers was 27 lbs., and the vacuum in the condensers 26 inches. She left Liverpool for Valparaiso on the 11th of the present month, with sufficient coals to carry her 5,000 miles at 240 miles per day, and a full complement of stores for the passengers on board; her draught of water on leaving Liverpool at the load line was, aft, 14 ft. 6 in.; forward, 13 ft. 9 in.; and displacement, 1,700 tons. She steamed to the Holyhead Light, where the pilot left her, at the rate of 11½ nautical miles per hour against a strong head wind; the engines were making 20 revolutions; the steam pressure was 26 lbs.; the vacuum 26 inches; and the consumption of coals 22 cwts. best Welsh coals per hour.

The engineers are now constructing the machinery for three other steam-ships on this principle, with boilers on the cellular cylindrical spiral principle. In conclusion, the form of engines now described gives regularity of motion, while working expansively to the fullest extent, the expansion principle is fully realised, and the engines are of a strong architectural figure, with the various parts easily got at, and reduced to simple forms, and present every facility for reversing freely by the engine-driver.

The performance of the Lima on a trial trip of considerable distance, namely, between Liverpool and Dublin, was made several months ago, under the observation of a member of the Steamship Performance Committee, appointed by the British Association at its last meeting at Leeds.

The member watched the performance of the ship and her machinery with the utmost minuteness, in conjunction with the Admiralty engineer; and an accurate return has been made to the committee, in accordance with the form prescribed and recommended for general adoption; and it

will be found on reference to the Report of the Committee on Steamship Performance, presented to the Association a few days ago, that all the dimensions and particulars of performance of the Lima are embodied therein.

The recorded performances of the Lima was not a mere *measured mile trial*, which may always be made to appear more favourable than practical experience afterwards attains, but was such an extended trial as the committee had previously recommended, and which recommendation was adopted by the Directors of the Pacific Steamship Company, the owners of the Lima.

SILAS'S MARINE LIGHTS.

MR. FERDINAND SILAS, inventor of the indestructible lights applicable for telegraphic purposes at sea, and also to point out the presence of life-buoys in case of shipwrecks or other such disasters, and which were exhibited for the approval of the Lords of the Admiralty in September last, in the presence of Commodore the Hon. Sir James Drummond, C.B., and the officers of Woolwich Dockyard, last night performed a course of experiments at Blackwall for the satisfaction of Admiral M'Hardy, Capt. F. R. Ward, members of the Royal National Lifeboat Institution Committee; Capt. Robertson, Surveyor-General; Mr. Lewis, Secretary; Mr. Grey, and other members of the Board of Trade who were present. The experiments commenced at six o'clock, when a number of the floating lights, attached to lines, were cast into the river from the pier. On floating to the surface, the phosphoric substance of which they are composed suddenly burst into a blaze of light, and was only extinguished by being dragged under the water. The apparatus intended for the telegraphic light resembles a moderator table-lamp. This was placed on the jetty near the water's edge, and was operated upon by the inventor. In spite of the opaque fog, which completely enshrouded the river from bank to bank, the strong glare of the phosphoric light penetrated for some considerable distance, and was gratefully acknowledged by several boatmen, who would otherwise have had great difficulty in making the pier. Similar experiments were entered into a few days ago in the presence of Admiral Gordon and the Brethern of Trinity House, together with the officers of the exploring ship Fox. It was then pronounced that the invention was extremely suitable for all the purposes above named, but they could not recommend the apparatus as applicable for lighthouses. In consequence of the deep obscurity in which the river was last night involved, and the difficulty of thoroughly carrying out the experiments, it was arranged, at the request of Admiral Hardy, that a second course of experiments shall take place at Blackwall on some future occasion.—*Times*.

STEAM SHIP ECONOMY.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."
GENTLEMEN.—Mr. Cheverton, I believe, admits the applicability of the formula based on the midship section (A); it therefore appears to me that he cannot object to my making use of this same formula expressed in terms of the displacement (D) unless he is prepared to question the geometrical fact that the corresponding sectional areas of similar bodies vary as the square of the cube root of the cubical contents, that is, when applied to shipping the midship sectional areas of the immersed bodies vary as the square of the cube root of the displacements. As many of your readers are now taking an interest in the theoretical performances of large ships in the reasonable hope that the Great Eastern will afford the opportunity of practically testing the value of such theoretical calculations, and as the essay (Steam Ship Capability, 2nd edition) to which I made reference in my letter of the 1st instant, being now out of print, is not readily accessible, and as the promotion of public discussion, with a view to public utility, is the only object that I have in publication, you would do me a favour, and perhaps some of your correspondents an acceptable service, by inserting

in the MECHANICS' MAGAZINE that portion of my essay which relates to the superior capabilities of large as compared with smaller vessels; and I take the liberty of enclosing a copy of this paper in the hope that you will publish it in the MECHANICS' MAGAZINE at your earliest convenience. As to Mr. Cheverton having understood that I am not the original discoverer of the formula referred to, I presume that he got that information from my own writings.

I am, Gentlemen, yours very obediently,
CHARLES ATHERTON.
Woolwich Dockyard, 14th November, 1859.

SHIPS' CHAIN CABLES.

M—T—, Nov. 10, 1859.
TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Your correspondent "Amicus," in connection with the destruction of the Royal Charter, has done much good, by enlightening the public upon the character of the iron plates used in the construction of iron vessels. There is one point, however, upon which his exposition is imperfect. I refer to the quality of the iron used in the *chain cables*, and I pray a short space for a few lines on that subject.

The first misfortune that we read of in this sad relation of the destruction of the Royal Charter is that after the anchors were cast the two cables *snapped*. The readers of the graphic article in the *Times*, "The Great Eastern in the gale," will not require to have their memories refreshed how the cables did duty in her case. We read—"In this last struggle some of the links of the chain cable were actually dragged out one-third longer, and one, which passed under the sharp bows of the vessel, was bent nearly double."

It is the writer's opinion had the Royal Charter cables been of the same quality as those of the Great Eastern that vessel and her cargo of precious metal and more precious lives would not have been lost. I have heard it stated and repeated that the proprietors of large vessels care not anything further about the quality of their cables, than that they stand the test required by the insurance offices. A very common or inferior iron cable will stand that test, when new. Yet such a strain may be received then, although the cable may not have snapped, that it would have been far safer to have used the cable without testing it. But with a superior quality of tenacious fibrous iron, no injury whatever is done to the cable by the test employed, and it would not be torn asunder without almost double the weight employed. I have spoken myself to cable manufacturers upon the impropriety of using common No. 2 bolts for making cables, and have received some such answer as that they received no complaints, and used the iron of the best makers. Is there no one to complain for the host of lives, as valuable as our own, which have been lost in the last fortnight's storms from this cause? I know nothing of the cables of the Royal Charter, but cannot help forming an unfavourable opinion of them, and suppose them to be no better than the plates employed.

The cables of the Great Eastern, as has been stated, were made by Messrs. Brown, Lenox, and Co., Cardiff, and of iron prepared for them at the works of Mr. Anthony Hill (Hill P F Co.); and the late Mr. Brunel had most emphatically requested Mr. Hill, that the best possible iron only should be provided,—and probably better iron was never seen than that used in the cables of the Great Eastern, and it was not a bit too good, as the proof as shown.

Allow me to close this subject in your own words. "This state of things should be remedied. In the name of Christian charity, let us not expose our fellow-creatures to violent deaths, 500 at a time, for the mere difference in the price per ton between good and bad iron." "VERITAS."

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I feel assured you will pardon me for bringing the attention of the public through your columns to the apparent ultimate cause of the loss of the noble steamer the Royal Charter

with 400 lives, viz., the breaking of the chain cables. Why did not the Great Eastern go ashore from the same cause? a ship for which there was no parallel to decide upon an adequate size of cable in comparison with any other ship afloat. Surely shipowners should not be allowed to fix the size of cables and anchors for their ships—a subject which nine out of ten know nothing whatever about—grinding the captain down to a 1½ inch in size, and urging the saving of a £5 note in the equipment of a noble ship. They should be compelled to take the best, and nothing but the very best, cables and anchors that can be made, and then the manufacturer would live by his own merit, and not by grinding down the wages of his unfortunate men. The very price they are now sold at is a sufficient guarantee that the articles must be rubbish. Where is England's maritime superiority? or where the feeling of a nation proud of its honourable dealings, while such wholesale slaughter is allowed for the saving of a few pounds in the outfit of her finest passenger ships? Owners assert that steamers do not require such good cables and anchors as sailing ships; surely this sad affair will open the eyes of the public. How is it that both screw and paddle, as exemplified in the *Times* account of the Great Eastern, are rendered useless by *debris*? mostly occasioned by the very means adopted to save the ship and lives, viz., the cutting away the masts, when nothing is left in the very jaws of death but the quality of the ship's cables and anchors.

A CONSTANT READER.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 ls. 8d., annually, payable in advance. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Our Weekly Gossip.

A REMARKABLE circumstance occurred on Wednesday in Portsmouth harbour.—It was H.M. ship Vulcan exercising, reefing and unreefing her topsails on the Cunningham system. It would have made the old tars of Benbow's time, or of a more recent age, stare to see the canvas disappearing as if by magic, and the area of the topsails, as it were, melting away without the appearance of any effecting cause; as at a distance the rotation of the yards could not be discovered. The Vulcan's exercise caused considerable interest in the harbour, and may be looked upon as an event in the Royal Navy. It was remarked by those who were on board that the senior-lieutenant, Lieutenant P. W. Stephens, had quite fallen into the new system as if he had known no other; and that although he had, as it were, to invent the routine of orders to be given as he entered into the exercise, there was no hesitation, but each order came out decidedly and distinctly. It is pleasant to see young officers of the service thus grappling so zealously and ardently with the improvements of the age, and it shows that although there may be some rust to rub off, we have some good solid material underneath to work upon. It has been before noticed that Commander Strach applied for the Cunningham system, and is entering into the change most earnestly and zealously. It will be by enterprising officers of this description that progressive improvement in the Navy will be effected.

The British Government (says the *New York Courier and Enquirer*), is drawing largely on the white oak forests of Virginia. Over three hundred men are now employed in getting timber in the mountains near Rowlesburg, on the Cheat River, which is to be used for gun carriages. The contractor has orders which it will take two years to fill. The Cheat River oak is said to be the best yet imported into England, and far surpassing the Canada oak, which it is fast superseding.

The Royal Engineers who are about to proceed to China will take out with them a large supply of all kinds of engineering stores and implements to be used

in sapping and mining and siege operations. The detachment is also accompanied by a party of photographers, provided with the best instruments used in photography, for taking views of the defences, earth-works, &c. Several of the Royal Engineers have also been instructed in laying down and working the electric telegraph, several miles of wire being taken out by the expedition. All the men have been supplied with clothing suitable to the climate of China at the expense of the Government.

A practical movement for the protection of all animals of draught from the inclemencies of the weather is on foot amongst a few wealthy and influential persons, who have already subscribed somewhat largely to this end. The movement more particularly applies to the cab-horses of the principal cities of Great Britain, which may be seen standing by night and day, mayhap for hours, with their loins—the most susceptible portion of the animal—exposed. The consequences are, that when the poor beasts have to be thawed into movement, the gutta-serena thong is applied with undue severity, the horses suffer frightfully, and "Cabby" gets fined for cruelty. The simple method by which it is intended to obviate this state of things is either to dispense gratuitously, or to sell at a nominal price, a proper covering for this portion of the animal's body, and arrangements have been entered into for this purpose with some well-known Government contractors, to provide a waterproof covering made of a cheap and recently patented material with this view. We cannot, however, refrain from expressing our fear that although the motives of the benevolent persons referred to are highly commendable, the scheme is liable, if indeed practicable, to great abuse, inasmuch as those for whom its benefits were never intended may find means of profiting by the dispersion of a useful article to be had for little or nothing. And that the Legislature will interfere to make it a compulsory act upon the part of the cab-masters, and others, to provide their horses with such a protection is almost too much to expect. There is certainly a good deal that is suggestive in the scheme, and it appears to us that "The Society for the Prevention of Cruelty to Animals" would do well were it to endeavour to merge these actively benevolent persons, and whatever portion of their plan may be found feasible, into their already valuable sphere of usefulness. The costermonger's donkey, the laundress's pony, &c., are to be admitted to the full benefits of this seasonable thoughtfulness.

Messrs. Versmann and Oppenheim desire us to put the following note on record:—

Chemical Laboratory, 7 Bury-court, St. Mary Axe, London, Nov. 12, 1859.

GENTLEMEN.—Will you allow us to add a remark to a notice on our researches on the salts best adapted for rendering fabrics non-inflammable contained in to-day's number of your valuable paper. The phosphate of ammonia is not to be recommended to muslin-manufacturers, on account of its high price, whereas the sulphate of ammonia has the advantage of being infinitely cheaper, while it is equally harmless and required in a smaller proportion. We therefore advocated the application of the latter only in manufactories, and of tungstate of soda in laundries, in a communication read before the British Association for the Advancement of Science, which has just now been published separately by Messrs. Trübner and Co., and which gives a detailed account of our investigation. We beg to send you a copy of this pamphlet, and we are, Gentlemen,

Your obedient servants,

F. VERSMANN, F.C.S.

A. OPPENHEIM, A.C.S.

The following communication will find its fittest place here.—

Woolwich Dockyard, 14th Nov., 1859.

GENTLEMEN.—The adverse tone of the commencement of your editorial critique in the MECHANICS' MAGAZINE of the 4th inst. on my suggestion of "Unsinkable ships," enhances the importance of the conclusion at which you have arrived in your editorial on this subject of the 11th instant, namely:

"Mr. Atherton's fundamental idea may be a good one; indeed, we have ourselves a presentiment that unsinkable war ships, at least for purposes of home defence, will one day be devised. Good may arise from the introduction of the subject to public attention. If the Council of the Society of Arts can adopt any means of hastening the realisation of Mr. Atherton's ideas, they too will earn the approbation of the public."

The subject being thus recommended for the consideration of the Society of Arts, it may be premature to anticipate their decision. I would merely observe how effectively the invitations of the Society of Arts

have, on many occasions, been responded to whenever through the action of that Society, the public mind has been directed to any public requirement. For example: within a week of the publication in the Society of Arts' *Journal* of the 28th ult. of my suggestion on "Unsinkable ships," I received communications from parties already prepared to take up the subject of the required material therein referred to; and it was a singular coincidence that in the very same journal an article appeared describing (with reference to a totally different subject) a new process for converting a certain solid substance into a cellular mass; and in the MECHANICS' MAGAZINE of the present week, we have the subject of rendering even textile materials unflammable practically treated of. Both these points are analogous to what is required in the present case.

I cannot doubt that if the Council of the Society of Arts should take up this subject, and be liberally supplied with the means of offering the premiums referred to, namely, first: For the material best adapted for the construction of unsinkable ships or rendering ships unsinkable; and, second, plans for the most effective application of such material for all cases of naval construction, I have no doubt that such action of the Society of Arts would call forth a display of chemical, mercantile, and constructive knowledge of no ordinary character, and, may be, of the greatest public utility.

I am, Gentlemen, your very obedient servant,

CHARLES ATHERTON.

A reliable gentleman favours us with the following statement of a very curious incident:—"The following extraordinary occurrence took place during the late severe gale at Ystrad Mynach, the seat of a friend of mine in Glamorganshire: an oak tree computed to be about 3½ tons weight, was blown fairly up by the roots and prostrated in the direction of the wind; the wind changed directly round and blew with increased violence, when the oak tree was lifted perpendicularly, and turned over in exactly the opposite direction to that in which it first fell. This fact was witnessed by one of the men, who was so alarmed that he ran from it as fast as he could."

An inquirer sends the following:—"Mr. St. Croix, in page 296, first column, of your last number, speaks of the screw fans being at an angle of 45° with the shaft. At the bottom of page 299, first column, he speaks of the fans being 45° degrees with each other. Is there not some mistake? If the fans are at 45° with the shaft (or axis) they must be at 90° with each other."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgment:—

STEAM ENGINES, &c., 885, 888, 893, 937.
BOILERS AND THEIR FURNACES, &c., 895, 932.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 890, 923, 931, 934, 939, 940.
SHIPS AND BOATS, including their fittings, 904, 907, 910.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 915, 926.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 892, 909, 917, 934, 935.
FIBROUS FABRIC, including machinery for treating fibres, pulp, paper, &c., 880, 887, 899, 905, 909, 916, 922, 936.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 908, 918.
LIGHTING, HEATING, AND VENTILATING, 867, 906, 911, 914, 925.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 868, 896, 919, 928.
METALS, including apparatus for their manufacture, 882, 915.
CHEMISTRY AND PHOTOGRAPHY, 879, 891.
ELECTRICAL APPARATUS, 861.
WARFARE, 864.
LETTER PRESS PRINTING &c., 899.
MISCELLANEOUS, 878, 882, 886, 894, 896, 901, 902, 908, 912, 920, 921, 924, 927, 929, 930, 933, 941.

878. M. A. F. MENNON. "An improved articulated joint for water, gas, and steam pipes." Dated April 8, 1859.

This invention is not described apart from the drawings. Patent completed.

879. M. A. F. MENNONS. "Improvements in the treatment of mineral phosphates of lime." (A communication.) Dated April 8, 1859.

The patentee claims the treatment of natural or fossil phosphates of lime by ammoniacal precipitation from their solution in hydrochloric acid for the production of a chemically pure and thoroughly soluble and assimilable phosphate of lime for agricultural purposes. *Patent completed.*

880. N. A. GRUMEL. "Improvements in dyeing cotton, wool, silk, flax, and other fibrous materials or fabrics." Dated April 8, 1859.

This relates to means of obtaining a fast black dye, and the shades thereof, without the use of indigo. *Patent completed.*

881. W. HOOPER. "Improvements in insulating and protecting telegraphic conductors." Dated April 8, 1859.

The patentee first coats the conductors with india-rubber, and afterwards applies over the first coat another coat consisting of india-rubber combined with sulphur. These two coats are separated the one from the other by a layer of a material which will prevent the action of the sulphur of the outer coating on the inner coating when the heat necessary to change the outer is applied. In order thus to separate the two coats the patentee employs a layer of thin metal. The second part of the invention consists in the production of a vulcanized or converted india-rubber coating on wire or other metal conductors which are coated with gutta-percha whether applied directly to the metal conductors or on to conductors which have previously been coated with tin or other protecting metal. *Patent completed.*

882. W. HOOPER. "Improvements in re-working or re-manufacturing compounds of india-rubber and sulphur." Dated April 8, 1859.

This consists in combining raw india-rubber and sulphur with the ground product of waste or old converted sulphur compounds of india-rubber, and subjecting the same to high degrees of heat to convert or change the same into elastic and hard compounds. *Patent completed.*

883. W. HENDERSON. "Improvements in treating certain ores and in obtaining products therefrom." Dated April 8, 1859.

This relates, 1, to the treatment of zinc ores, or other ores containing zinc. 2. To the treatment of ores of antimony that contain lead and other metals. 3. To the treatment of copper ores. 4. To the treatment of ores or products containing cobalt. 5. To the treatment of gold and silver ores and auriferous quartz. We cannot possibly give space to the voluminous details of this invention. *Patent completed.*

884. W. E. NEWTON. "Improvements in telegraphing and in telegraphic apparatus." (A communication.) Dated April 8, 1859.

This consists in an arrangement of telegraphic apparatus that shall not be susceptible to the changes of the weather, and that shall generate an amount of inductive electricity that shall answer all demands. The invention is not described apart from the drawings. *Patent completed.*

885. E. R. HANDCOCK. "Improvements in steam and other motive power engines." Dated April 8, 1859.

This consists in the use of an additional crank loose on the axle, and placed at such an angle as will give sufficient leverage to put the shaft in motion at the first starting of the engine, and to force or aid the crank over the dead points. In some cases the patentee uses a single bolt inserted into a piece of metal which is firmly fixed to the shaft, so that the bolt may be acted on by means of a cradle or other convenient arrangement; when reverse action is required two bolts suitably fixed are used. *Patent completed.*

886. T. SPENCE. "Improvements in the economical treatment of refuse or wash matter containing sulphur." Dated April 9, 1859.

The patentee claims the use of the oxides, ores, and other compounds of iron and the oxides of manganese for the obtaining of sulphur from the hitherto refuse or waste matters. *Patent completed.*

887. E. J. HUGHES. "Improvements in the manufacture of woven fabrics." (A communication.) Dated April 9, 1859.

Here the warp and welt threads are arranged so as to obtain an improved mode of threading or tramping. The improved method of making the fabric dispenses with the use of temples, and weaves with much less strain upon the cloth, thus requiring less weight on the yarn beam, and allowing the loom to be worked at a greater speed. *Patent abandoned.*

888. T. BARNETT, H. T. SOUBUTS, and W. LOYD. "Improvements in steam-engines." Dated April 9, 1859.

This consists in a method of supplying the feed-

water to steam-boilers at a higher temperature than has hitherto been obtained. *Patent completed.*

889. J. H. YOUNG. "Improvements in setting-up (composing) and distributing types." Dated April 9, 1859.

Under that part of the composing machine at which the types issue to be collected into a line the patentee places a propeller to propel the types as they stand in the receiver, and over this propeller he causes the types to tilt so that the head of the type issuing from the composing machine, and about to fall into the receiver, shall be raised so as to prevent the tail of the type immediately following from passing over it. With reference to distributing types, when a reservoir is used to hold types of uniform thickness, the aperture which regulates their exit may be of a determinate size, but when the reservoir is intended for all the sizes of a fount the patentee has found the following arrangement useful:—In front of the exit aperture he places three or four thin blades of metal each provided with a spring and connected by a catch bar, with the pusher that sends the types out of the reservoir. The pusher is made as thin as the thinnest type used, and so are the blades in front of the exit aperture. The patentee next describes the mode of operation, which we cannot quote here. *Patent completed.*

890. J. HAWKINS. "Certain improvements in the manufacture of stirrups, bits, spurs, buckles, and other such like articles connected with harness and saddlery." Dated April 9, 1859.

This invention is not described apart from the drawings. *Patent completed.*

891. J. H. JOHNSON. "Improvements in the manufacture or production of the ferrocyanide and cyanide of potassium." (A communication.) Dated April 9, 1859.

For the manufacture of prussiate of potash it is proposed to melt the carbonate of potash in a cast iron vessel with water, and then to add thereto a sufficient quantity of wood, charcoal, or coke, to completely imbibe the solution of carbonate of potash. The whole is now heated until the charcoal or coke becomes thoroughly dry. The carbonate of potash will then be found distributed in the porous and spongy mass. This mass, with the addition of five parts by weight of iron filings, is introduced into two retorts communicating with each other by a pipe which connects the upper part of one retort with the lower part of the other. The retorts are now heated to reduce the carbonate of potash to the state of peroxide of potassium, whereupon by the introduction into the retorts of a current of ammoniacal gas whilst the retorts are at a white heat, the yellow prussiate of potash will be obtained. The gas enters the bottom of the first retort containing the charcoal, and acting on the potash cements it into prussiate of potash. On leaving the first retort the gas enters the bottom of the second retort, and finally escapes by a pipe or chimney. The manufacture of the cyanide of potassium is accomplished in a precisely similar manner, with the exception that the iron fittings are dispensed with. *Patent completed.*

892. R. J. DERRHAM. "Improvements in cheese-vats." Dated April 9, 1859.

This consists in forming a vat of staves with galvanized or not galvanized spring hoops, so that the hoops may open the staves, and thereby easily disengage the cheese from the vat. *Patent abandoned.*

893. J. MARTIN. "Improvements in the materials used in the manufacture of bonnet-fronts and ruches." Dated April 9, 1859.

This consists in the application of a band of cotton or linen tape to the back part or folded edge of bonnet fronts and ruches. It also consists in introducing a strip of pasteboard, &c., instead of wire within the band. *Patent completed.*

894. C. F. VASSEBOT. "A new motive power applicable to tanneries." (A communication.) Dated April 9, 1859.

This consists in a horse mill the power of which is employed to put in motion by means of bands and pulleys a certain number of cylinders mounted upon shafts and turning upon pivots. *Patent abandoned.*

895. W. E. NEWTON. "Improvements in steam-engines and boilers." (A communication.) Dated April 9, 1859.

This relates, 1, to a novel mode of communicating the motion of the piston or pistons of the engine to the crank shaft. 2. To the condensation of the steam after it has acted on the piston or pistons. 3. To the mode of supplying or distributing it to or in the cylinders, and of conducting it therefrom to the condenser. 4. To the production or generation of steam in boilers with a moveable furnace or fire-place of an annular form. The invention is not described apart from the drawings. *Patent completed.*

896. H. F. GARDNER. "Improvements in ma-

chinery for blocking or crimping the uppers of boots and shoes, and in treeing boots." (Partly a communication.) Dated April 9, 1859.

This includes a variety of detail in connection with blocking, crimping, and treeing to which we cannot devote space. *Patent completed.*

897. R. BROWN. "Improvements in stoves and apparatus for warming and ventilating apartments and buildings." Dated April 9, 1859.

This stove is made of metal or earthenware, or both combined, and burns either gas or ordinary fuel. It is constructed so as to admit into an apartment fresh air from the external atmosphere, and to warm it by contact with certain heating surfaces (which we cannot more particularly allude to) and to pass it warmed into the apartment or building to be warmed or ventilated. *Patent abandoned.*

898. B. BAUGH. "Certain improved arrangements for working fly presses by steam, water, or other power." Dated April 11, 1859.

This consists in producing a continuous elevating and descending action of the press by means of certain combined arrangements which we cannot here allude to in detail. *Patent abandoned.*

899. R. WAPPENSTEIN. "Improvements in cop tubes, and in machinery or apparatus for placing the same on the spindles used for spinning and doubling fibrous materials." Dated April 11, 1859.

The patentee makes the tubes of white metal, and casts them in moulds having grooves or other patterns so that the tubes shall be grooved, screwed, or indented on their exteriors to prevent their slipping in or out of the cop after it is built. He places any convenient number of the tubes on the spindles at one and the same operation by placing them in a clipper formed of two pieces of wood, metal, or other material so as to hold all the tubes or a division of them until they are required to be lowered on the spindles. *Patent completed.*

900. W. SCHOFIELD. "An improved effervescent lemonade." Dated April 11, 1859.

This lemonade is composed by mixing together the following ingredients:—Rich Malaga wine $\frac{1}{2}$ pint, essence of lemon, 30 drachms, sugar, 8 lbs., acid of lemon, 3 oz., water, 3 quarts and $\frac{1}{2}$ pint to a gallon of liquor, to which is added the aerated water. *Patent abandoned.*

901. J. ANDERSON. "Improvements in the construction of the furnaces of bakers' ovens for the purpose of consuming smoke, which improvements are also applicable to the consumption of smoke in other furnaces." Dated April 11, 1859.

Here the inventor provides an additional flue which is carried into the main flue in the oven. In the additional flue he inserts a damper for regulating the supply of air to the main flue. The air flue thus terminating in the chimney, the boiler or oven receives the full benefit of the flames without the temperature by the direct introduction of cold air. Dampers are provided in the furnace to regulate the strength of the draught. *Patent abandoned.*

902. W. BOALLER. "Certain improvements in the manufacture of soap." (Partly a communication.) Dated April 11, 1859.

This consists, 1, in mixing stearite with silicate of soda and introducing it into any and every description of soap. 2. In mixing stearite with the ordinary soda of commerce, and employing them during the process of the manufacture of soap. 3. In the use of either of these two articles in combination with stearite in the manufacture of soap. *Patent abandoned.*

903. L. WIMMER. "An improved preparation for killing beetles." Dated April 11, 1859.

This consists of a mixture of alumina containing various dissolved or oxidised metals and earth, farina of peas, borax and sugar in suitable proportions. *Patent abandoned.*

904. A. BOWERS. "Improvements in or applicable to keels of navigable vessels." Dated April 11, 1859.

Here moveable pieces are attached to the bottom of the ordinary keel by a hinged joint, so that it may be set at any angle required by mechanical means which can be acted upon from the interior or deck of the vessel. *Patent abandoned.*

905. W. ROWAN. "Improvements in spinning flax, hemp, and other fibrous materials." Dated April 11, 1859.

This relates to machinery to be used in preparing flax, hemp, China grass, and other similar fibres in order to fit them for being spun into yarn. In lieu of the screws now used in screw gills the patentee uses screws the pitch of which is variable, so as to produce a corresponding variable motion in the gills instead of a uniform motion, whereby the drawing action on the fibres is more effectually performed than in the machines now in use. *Patent completed.*

906. R. A. BROOMAN. "Improvements in candle-

moulds." (A communication.) Dated April 11, 1859.

This consists in fitting to moveable nozzles used in candle-moulds a spring or springs, whereby the nozzle may be pressed down to drive the finished candle from the mould, after which the nozzle will return to its original position by the pressure of the spring or by the wick needle, in which position it will be retained by the spring or springs. *Patent completed.*

907. W. S. CLARK. "Improved means of loading ships or vessels with coal, and of separating or removing small coal therefrom." Dated April 11, 1859.

The patentee claims loading ships with coal by means of boxes or tubs into which the coal is delivered from the chute, and by which it is lowered through the hatchways into the hold. He also claims forming the chute with screens through which the small coal will pass, and falling into lower shutles will be conducted back to the quay or discharged into any suitable receptacle instead of being allowed to pass into the ship. *Patent completed.*

908. W. H. BARLOW. "Improvements in beams and girders." Dated April 11, 1859.

This relates to beams and girders which have one or more intermediate supports, in addition to the two terminal bearings, and the invention consists in constructing beams or girders with an increased depth of beam or girder over or near the piers or intermediate points of support, by which the patentee not only obtains greater strength over the piers or intermediate points of support with the same quantity of material in the flanges, but the radius of curvature of the upward flexure is rendered greater, that is to say, the curve is flatter and the points of contrary flexure are thereby moved nearer to the centre of the span, so that the sectional area of metal in the flanges, throughout the centre portion of the beam between the points of contrary flexure, may be considerably reduced, without diminishing the strength of the beam when compared with a beam of equal section. *Patent completed.*

909. J. MARLAND. "An improvement in the manufacture of cop tubes." Dated April 11, 1859.

This consists in applying gutta-percha, glue, or other cement over the whole surface of the paper or material, into the desired angular forms for making cop tubes; and after the paper or material has been cut into proper forms, and allowing it to set or dry before cutting the paper or material, in applying a fluid solvent, or heat, or both to render the cement adhesive as the material is wound round a suitable spindle or mandril. *Patent completed.*

910. W. CLARK. "An improved safety block to be used for lowering ships' boats, the same being applicable to other like analogous purposes." Dated April 12, 1859.

The block with its sheave or sheaves is constructed in the ordinary manner, but has attached and secured to the bottom or lower part thereof a hook, which the patentee calls a tumbling hook. *Patent completed.*

911. D. DOIG. "Improvements in the construction of gas lamps." (A communication.) Dated April 12, 1859.

This consists, 1, in the use or application of glass prisms or triangular or nearly triangular pieces of glass placed horizontally or nearly so in or on to the upper part of steel or other glass lamps. 2. In the substitution of glass that is combined with metal for, and instead of, the ordinary tin or other opaque framing steel gas lamps. *Patent completed.*

912. P. ARCHIBOX. "Improvements in taps." Dated April 12, 1859.

Here the patentee forms the valve of leather encased in brass, and constructs the valve seat with a projecting rein concentric with the circumference of the orifice therein. The valve is attached to the key, spindle, or plug, which works in a screw collar and closes the valve upon the projecting seat, or removes it therefrom, according to the motion imparted to it. The pressure of the water (which ordinarily causes vibration of the valve when open, and intermittent action) is regulated where the supply pipe is attached by the diameter of the inlet orifice of the tap. *Patent completed.*

913. G. J. JOHNSTON. "Improvements in drills, for drilling of corn, seeds, and manure." Dated April 12, 1859.

Here the drill coulter has a rotary motion working on its own axis; it is self-acting, and self-cleansing for cutting of the earth, and for depositing corn seeds and manure, and can be so fixed as to penetrate the ground to any depth that may be required, and can be applied to any drill now extant. *Patent abandoned.*

914. E. T. NOUALHIER. "An improved ventilator." Dated April 12, 1859.

This consists of a cylinder to the upper part of which a tube for the entrance of air is soldered so as to communicate with the interior. To one end of the cylinder a pipe is adjusted which passes through, and extends a short distance beyond, its opposite end, to which opposite end of the cylinder is soldered another tube of larger diameter than the first (with which it forms one whole), so as to leave a small space between it and the first tube for the egress of air from the cylinder. Thus the air entering the top pipe passes into the cylinder, and afterwards into the large and smaller tubes, forming thereby a double current of air. *Patent abandoned.*

915. W. E. NEWTON. "Improvements in the manufacture of iron." (A communication.) Dated April 12, 1859.

This chiefly consists in the combination of the blast chamber and pipe with what is called the dust plate, and also in delivering a blast of air into the liquid iron in the hearth of the blast furnace by a trigger or blow pipe introduced into the front part of the hearth between the dam and the tump, the said trigger or blow pipe being pushed down at an angle of about 90 degrees into the blast chamber through the dust plate, clay, crust, and the fluid cinder down to near the bottom of the liquid iron in the hearth. *Patent abandoned.*

916. P. HILL and J. MOORE. "Improvements in weaving double pile fabrics." Dated April 12, 1859.

Here six warp beams or rollers are employed, and eight beams of heddles. Two of the six rollers or beams have the ground warps wound thereon, and the pile warps are wound on to the other four beams or rollers. The ground warps are passed through and actuated by four leaves of heddles, and the pile warps are passed through and actuated by four leaves of heddles. The batten or slay is caused to beat up twice for each weft, and the shed in the warps is changed between the two beats. An extra leaf of heddles is used to divide the warps to keep the warps clean. This extra leaf of heddles remains stationary during the process of weaving, no eyes being used therein, but only single head threads, between which the warp threads move up and down thus clearing themselves. The cleared leaf of heddles is set at the back of the other leaves of heddles. *Patent completed.*

917. C. BURRELL. "Improvements in apparatus for screening corn and seeds." Dated April 12, 1859.

Here a screen is suspended on four rods which at their lower ends are pin-jointed to the screen, and at their upper ends are pin-jointed to the ceiling, so as to admit of the screen swinging to and fro when actuated by a crank and connecting rod, or by other means. Two of the suspending rods are longer than the other two in order that the screen may assume an inclined position. Below the screen a series of rods are fixed, which are arranged in pairs, and each pair has a series of scrapers or blades strung on it, there being as many scrapers or blades on each pair of rods as there are spaces between the longitudinal wires of the screen, and there are as many pairs of rods as there are divisions formed by the transverse wires in the length of the screen. The scrapers or blades are kept separate by washers placed between them, which are also strung on the lower of each pair of the fixed rods. *Patent abandoned.*

918. M. CASTAY. "Improvements in metallic bridges." Dated April 12, 1859.

This relates to a new system of cast and wrought iron bridges formed of parts jointed together. The invention is not described apart from the drawings. *Patent completed.*

919. J. CROSSDALE. "Certain improvements in boots and shoes." Dated April 12, 1859.

This consists mainly in interposing perforated tubes of elastic material between the insole and outer sole of boots and shoes, the said tubes being connected with the external atmosphere by openings formed in the upper, sufficiently above the sole of the boot and shoe to prevent the entrance of wet and dirt. It is proposed to insert eyelets into the several perforations in the aforesaid tubes, and to connect such perforations to or with other perforations made through the insole of the boot or shoe. *Patent completed.*

920. J. WARD. "An improvement or improvements in working fly presses used for raising metals, coining, and other like purposes." Dated April 12, 1859.

The inventor applies a steam cylinder to the top of the screw of the press, the piston of the steam cylinder passing through both the bottom and top of the cylinder. The lower end of the piston rod is coupled to the top of the screw by a coupling which permits the screw to rotate without the rotation of the piston rod. The upper end of the piston rod acts

upon the slide valve of the cylinder so as to admit steam under the piston when the screw is rising, and to admit steam above the piston when the screw is descending. *Patent abandoned.*

921. R. A. BROOMER. "Improvements in the preparation of red dyes." (A communication.) Dated April 12, 1859.

These new dyes, called by the inventor "Fuschine," are prepared by heating together to the point of ebullition a mixture of aniline and of anhydrous bi-chloride of tin. *Patent completed.*

922. S. TATTON. "Improvements in preparing and treating silk, and improvements in dyeing silk." Dated April 12, 1859.

This consists, 1, in preparing raw silk, silk thread, sewing silk and silk twist, (commonly called barber's sewings or boot twist) before or after being dyed any colour except black, and whether manufactured into thread or twist or not, by submitting the silk to a bath of sugar, or of sugar and gum, or to a bath of any other suitable glutinous substance. 2. In dyeing raw silk, silk thread, sewing silk, and silk twist yellow and gold colours, and all shades thereof, by submitting the silk first to a bath containing anatto and soap; second, to a bath containing muriate of tin, or other solutions of tin or salts of tin; third, to a bath containing Persian or Turkey berries. *Patent completed.*

923. R. EMBRY. "Certain improvements in carriages for common roads." Dated April 12, 1859.

This invention is not described apart from the drawing. *Patent completed.*

924. W. A. MARTIN and J. PURDIE. "Improvements in fire-bars." Dated April 12, 1859.

The sealing of this patent is opposed, and the papers relating thereto cannot be seen.

925. H. ECKHORN. "Improving and regulating the production of light in lamps, to which he gives the name of "Universal Lamp Regulator." Dated April 12, 1859.

This lamp regulator is formed by a moveable cylinder which is introduced into the lower part of another moveable concentric cylinder, which latter is closed at the top. This regulator may be contracted or enlarged, raised or lowered, so that the admission of air to the lamp is under perfect control. *Patent abandoned.*

926. R. COLEMAN. "Improvements in agricultural implements." Dated April 12, 1859.

This relates to two previous patents of the patentee, which embody various improvements in implements known as cultivators, and consisting of a number of tines, hoes, ploughs, &c., mounted on fulcrums, and all having communication with a barrel spindle, by motion from which they are inserted or removed from the soil, and the depth of the insertion regulated. According to the present invention, the patentee furnishes implements of this class with a double set of tines, scarifiers, hoes, &c., to act in opposite directions to each other, so that there is no necessity to turn round at the headlands. To move machines of this class a sufficient breadth sideways, he mounts all the carrying wheels on swivel supports, and so arranges and connects them that they may be all moved on their axes simultaneously by hand gear in connection therewith. Another part of the invention relates to such agricultural implements as are mounted on wheels, and turn round at the headlands, or otherwise to act and traverse in the opposite direction. To facilitate the turning, he mounts a cross rod between the hind wheels, and connects with it a hand lever, by which the attendant moves the cross rod so as to lock either one of those wheels according to the direction in which it is desired to turn. *Patent completed.*

927. J. APPERLY and W. CLISSOLD. "An improved construction of fulling machine." Dated April 12, 1859.

This relates to the rollers of fulling mills, the object being to perform the fulling with little friction. The inventors use but one pair of fulling rollers, mounted horizontally in the fulling mill, and drive them in the usual way. The endless band of cloth to be milled is passed over guide rollers, and between a pair of driven nipping rollers, which are situated immediately above the fulling rollers. These rollers draw the cloth forward, and allow it to drop into the bite of the fulling rollers, by which it is fullled or milled while in a slack state. To facilitate the traverse of the cloth over the bottom of the mill-case, they employ a reciprocating pusher, which being placed below the fulling rollers, will drive against the cloth as it falls from the fulling rollers, and push it forward in folds to the other end of the mill-case, whence it is drawn up over the guide-rollers, as above explained. *Patent abandoned.*

928. W. CRAFT and T. WILSON. "Improvements in the manufacture of pinafores and bibs for children." Dated April 12, 1859.

The patentees make bibs of a light water-proof material, and form the lower part with a trough or gutter of the same, so that any liquid coming in contact with the outer surface of the bib, will run down into the gutter. *Patent completed.*

929. A. R. JOHNSON. "An instrument for damping, severing, and affixing postage and other like stamps." Dated April 13, 1859.

The patentee claims the construction of an instrument for damping, severing, and affixing postage and other like stamps in which the motion for severing and stamping is made to act upon the feed-wheel or wheel, and to advance a fresh stamp ready for the next operation. *Patent completed.*

930. J. A. CORREY. "Improvements in apparatus for heating liquids." Dated April 13, 1859.

This consists in introducing surfaces heated by steam, superheated steam, hot liquid, or hot air into the interior of the vessel containing the fluid to be heated, for which the patentee places therein a suitable heating vessel filled with direct passages proceeding from the bottom to the top, and open both at top and bottom, but having spaces between such passages closed in. *Patent completed.*

931. W. A. GILBERT. "Improvements in the construction of the axles of railway and other carriages." (A communication.) Dated April 13, 1859.

The object here is to render the two wheels of the same axle able to turn independently of each other, and the invention consists in the use of a second hollow iron axle, serving as an envelope to the inner axle. One of the wheels is fixed on the hollow axle, and the other on the inner axle, the hollow axle being bored internally so as to permit the inner axle, which is turned in a lathe, to play within it freely. The hollow axle extends from the external part of the nave of the wheel fixed to it to the interior of the nave of the wheel adapted to the inner axle; its length may, however, be modified according to requirements. The inner axle supports the weight of the carriage. *Patent abandoned.*

932. J. L. STEVENS. "Improvements in fire-grates of locomotive, marine, and other furnaces." Dated April 13, 1859.

This invention was described and illustrated at page 264, No. 43, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

933. J. HUGHES, W. WILLIAMS, and G. LEYSHON. "Improvements in the manufacture of tin andterne plates." Dated April 13, 1859.

Here in place of putting the plates after they have passed through the "wash-man's" pot into a pot of hot grease, the patentees place the plates in a rack contained in another pot of hot metal, and when the rack is full they raise it slowly out of the pot. While the plates are thus being raised out of the liquid metal, the superfluous metal runs off, and when the plates are cooled, which they are allowed to do in the rack, they are finished. *Patent completed.*

934. J. GILBERT. "An improved mill used for grinding, crushing, and reducing bones and other mineral and vegetable substances." Dated April 14, 1859.

This invention is not described apart from the drawings. *Patent completed.*

935. J. LUIS. "A new cooling apparatus for liquids, especially beer." (A communication.) Dated April 14, 1859.

This mainly consists in the use of an apparatus composed of a number of tubes through which cold water is caused to circulate, entering at the bottom, and ascending, and passing out heated at the top. *Patent completed.*

936. T. BIRD. "Improvements in the application and use of a certain natural product or products in the manufacture of pickers for looms, drawing rollers for spinning machinery, cop tubes, and for steps and brushes generally where lubrication is required." Dated April 14, 1859.

The patentee uses the nuts known as the Coquilla nut (*Aitalea purifera*) and the vegetable ivory nut (*Phytolophas marocarpa*), which, from their oily nature, require no additional lubricating matter, and are applicable to the above purposes. For pickers for looms he puts a bush made of the said substance in the tube, bush, or barrel of the picker, which runs on the spindle, whether the said tube be made of buffalo hide, wave metal, or other material, and he makes the picker of a single T shape, the tube at the top forming the top part without any slot for the picking strap, the picking strap being fixed round the tube and the centre of the picker; the bush or barrel may also be bounded with caoutchouc, leather, buffalo hide, or other suitable substance. *Patent completed.*

937. H. C. COULTHARD and J. JORDAN. "Certain improvements in steam engines." Dated April 14, 1859.

This consists, 1, in introducing a second facing and also an upper portion of the valve which is to work or slide upon the said extra facing. The steam being admitted between the top and bottom portion of the valve, it exerts pressure upwards against the top, and relieves the bottom or steam tight surfaces from a great amount of pressure. 2. In a method of adjusting the valve to the facings by means of a screw and internal spring to render such adjustment slightly elastic; by means of which improvements the wear of the sliding surfaces is much diminished, and an easier and more smooth action of the eccentric is effected. *Patent abandoned.*

938. J. BEATTIE. "Improvements in the means of preventing locomotive engines and carriages in motion on railways leaving or running off the rails." Dated April 14, 1859.

Here a suitably formed ring of metal is cast on, or affixed in one or more pieces, to the inside of the boss of each wheel, with a lip or turned-down edge, and on the axle of each wheel there is a ring of metal with a lip or turned-up edge, so placed that such turned-up edge or lip will come between the turned-down edge and the boss of the wheel, so that if the axle break between such turned-up edge and the boss, the lips or edges will preserve it in a horizontal position or nearly so, and preserve the engine or carriages on the line of rail. For the same object the patentee has in some cases an additional or check rail parallel with the ordinary rails at convenient positions on inclines or curves and other suitable parts of the line of rails, and he fixes such check rail in a channel or groove in the chairs of the railway or in a suitably formed chair for the purpose, or by other means, and bolts such check rail to the ordinary chair rail or sleeper. *Patent completed.*

939. E. PARTRIDGE. "An improvement in the manufacture of 'pipe' boxes for cart and waggon axles." Dated April 14, 1859.

This consists in forming conical steel bearings in the ends of conical cast iron boxes by casting the iron on to two conical collars shaped and prepared to fit the axles to which the boxes are to be fitted. After the boxes are cast the patentee hardens them in water. The two collars take the entire bearing of the axle and the space left between them and the axle, when in the box, forms a grease chamber. *Patent completed.*

940. W. BARNES, S. PICKERING, and J. ROBERTS. "Improvements in retarding and stopping railway locomotives and trains." Dated April 14, 1859.

This consists in the application of an additional cylinder on one or both sides of the engine, the piston-rod or rods of which are connected by a rod to the same crank pins on the driving wheel or axle, or to the engine cranks. The piston rod of the second cylinder is fitted so as to slide through its piston, but has a stop on it with an elastic packing or buffer, which confines it to the rod, and prevents contact with the bottom end of the cylinder. This cylinder is placed in communication with the boiler by a steam pipe and cocks, or valves and connecting gear, so that while the steam is turned off from the engine it is admitted to this second cylinder between the cover and the piston. The steam so admitted produces an elastic obstruction to the further rotation of the driving wheels, or the wheels with which such cylinder may be placed in communication, and so retards and ultimately stops the train. Eduction pipes are also provided, the eduction being controlled by valves or cocks. *Patent abandoned.*

941. E. DOWLING. "Improvements in parts of scales or weighing machines, and in balance weights used for those articles, which are also applicable for other purposes." Dated April 14, 1859.

This comprises various improvements in scales and weights, and consists chiefly in the adaptation of glass to the manufacture of the same. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Aug. 17, 1859.

1894. A. V. Newton. Improvements in the construction of carriages, and in apparatus for guiding or reining in carriages horses. (A communication.)

Dated Aug. 24, 1859.

1892. G. Riley. Improvements on helical refrigerators for cooling brewers' and distillers' worts.

Dated Sept. 13, 1859.

2083. A. B. Seithen. Improvements in apparatus for shaping cork stoppers, and in the manufacture of life-buoys and buffers of cork.

Dated Sept. 20, 1859.

2144. L. Matthews. Improvements in machinery to be employed in introducing plain or coloured wire upon lace or other fabrics, for the purpose of orna-

menting the same, or for running on and stiffening caps, cap-borders, or for other similar purposes.

Dated Oct. 4, 1859.

2250. T. Cook. Improved tools for making screws.

Dated Oct. 5, 1859.

2258. R. Fisher and C. Aspray. Improvements in photographic stereoscope slides, and in the stereoscopes employed in viewing the same.

Dated Oct. 10, 1859.

2298. J. Bentley and H. J. Sillem. Improvements in breech-loading fire-arms, and the machinery for manufacturing projectiles for small arms.

Dated Oct. 14, 1859.

2340. J. F. Conscience. A new and improved process of making bread, and certain machinery connected with it.

Dated Oct. 15, 1859.

2356. M. Henry. An apparatus for washing hanks skeins, threads, and yarns of silk and other fibrous materials. (A communication)

Dated Oct. 19, 1859.

2398. R. Hobson. Improvements in producing ornamental devices in glass or other transparent substances, for decorative or other purposes.

Dated Oct. 25, 1859.

2436. W. C. Day. Improvements in stockings and drawers, and other articles of under clothing.

2438. J. M. Napier. Improvements in printing machines.

2440. H. C. Hurry. Improved apparatus for applying or using magnetism or electro-magnetism as a motive power.

Dated Oct. 26, 1859.

2442. A. McGlashan. Improvements in refrigerators for cooling worts and other liquors.

2444. J. J. Bourcart. Improvements in mules for spinning.

2446. W. W. Kennedy. Improvements in shirts.

2448. J. W. Hackworth. Improvements in dynamic valve-gear, applicable to locomotive, marine, and other engines.

2450. J. Armour. Improvements in apparatus for measuring and for regulating supplies of solid and fluid substances in the preparation of mixtures or compounds.

2452. R. Christy, jun. Improvements in means or apparatus for securing the closing of doors.

Dated Oct. 27, 1859.

2454. I. Zacheroni. Improvements in electric telegraph cables for submarine and subterranean uses, and in submerging the same.

2456. P. D. Mickles. An automatic railroad switch. (A communication.)

2460. H. Phillips and J. Bannehr. Improvements in the manufacture of manure.

2462. R. A. Brooman. Improved threads for weaving, and a machine for making the same, which is also applicable to the winding or coating of one thread with another. (A communication.)

Dated Oct. 28, 1859.

2464. A. B. Mitchell. A new or improved pen-holder.

2466. J. Plantier. Improvements in brushes and brooms.

2467. D. Dillies. Innovations in weaving looms.

2469. J. F. Cole. Improvements in time-keepers.

2470. J. J. Baranowski. Improvements in railway signal apparatuses.

Dated Oct. 29, 1859.

2471. G. Ghesquiere. A process to render gold and silver malleable and ductile.

2473. S. C. Lister. Improvements in dyeing silk, cotton, and china grass, and similar vegetable fibre, and in preparing and spinning coloured and mixed coloured yarns from such fibres.

2474. C. Stannet. Improvements in apparatus used in the manufacture of boots and shoes or other coverings for the feet.

2475. J. S. Margetson. Improvements in collars for gentlemen's, ladies' or children's wear.

Dated Oct. 31, 1859.

2477. J. A. Turner. Improvements in rendering paper waterproof.

2479. T. C. Newby and J. A. Rainé. Improvements in portable bedsteads and spring mattresses.

2480. J. Ingham and G. Collier. Improvements in the manufacture of fabric, of the character of that technically called "camel," also in the winding of yarn employed in the production of such fabric, part of which improvements is applicable to other weavings.

2481. J. Bolton. Improvements in means or apparatus for winding thread or yarn on to shuttle

bobbins, or pirns, which improvements are also applicable in winding on to other bobbins, or spools, or tubes.

2483. R. A. Brooman. Certain plastic compositions to be employed for building and decorative purposes, and in lieu of marble, stone, brick, and cement. (A communication.)

2484. R. Cichowski. Improvements in ploughs.

2485. J. Holmes. An improved halter-block for stable purposes.

2487. L. Pohl. Improvements in fastenings for bags, purses, and similar purposes.

Dated Nov. 1, 1859.

2488. C. and I. A. Read. A new or improved tap or stop cock.

2489. W. Spence. An instrument for taking and registering deep sea soundings. (A communication.)

2490. A. V. Newton. An improved mode of and apparatus for condensing and cooling vapour and fluids. (A communication.)

2491. J. Jones. Improvements in shipbuilding.

2492. W. H. Perkin. Improvements in the manufacture of colouring matters.

2093. R. De Bary. Improvements in machinery for the manufacture of cigars. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(From the London Gazette, Nov. 18, 1859.)

1591. R. A. Brooman. Cementing, refining, and steelifying iron. (A communication.)

1606. S. Lloyd. Cast steel tyres.

1608. B. Seed and T. Steel. Treating soap-suds.

1609. J. T. Edmonds. Winnowing machines.

1615. Sir F. C. Knowles. Iron castings.

1616. J. Smith. Propelling.

1619. G. Ellis. Muffs.

1623. J. Gibbs. Brushes, &c.

1629. W. H. Harfield. Capstans and riding bits.

1630. H. Brinsmead and J. Lawrence. Screens.

1631. J. Taylor. Walls.

1632. T. D. Duppa. Carpenters' benches.

1634. W. N. Nicholson. Machines for making hay, and for cutting thistles, &c.

1635. W. N. Nicholson. Clod-crushers and rollers.

1642. J. Smith. Heating and cooling water.

1644. R. Clegg. Machines for cutting. (A communication.)

1653. C. J. Proal. Fabrics. (A communication.)

1656. W. A. Mann. Reaping machines.

1670. R. Longstaff and A. Pullan. Traction engines.

1678. W. O. Carter. Sawing slate.

1695. W. H. Harfield. Getting ships' anchors.

1698. J. Luis. Axle-trees. (A communication.)

1706. Z. G. A. N. P. Orioli. Bleaching and dyeing.

1726. W. H. Harfield. Capstans, riding bits, and stoppers.

1746. W. Hudson and C. Catlow. Looms.

1754. W. Clark. Turning over music leaves. (A communication.)

1776. T. W. G. Treeby. Targets.

2042. J. L. Jullion and G. Pirie. Gelatine.

2178. G. Addenbrooke. Raising and lowering boats.

2262. W. E. Newton. Blankets for printing. (A communication.)

2316. J. Skerthey. Tiles and slabs.

2328. C. P. Moody. Raising crops on to stacks.

2361. S. Newberry and H. Moore. Looms.

2392. C. Seton. Wheels.

2394. G. Hart. Hats.

2410. G. T. Bousfield. Steering. (A communication.)

2416. W. Fox and J. Willis. Umbrellas.

2423. F. N. Clark and C. Thomas. Choppers.

2430. E. Ellis. Lace.

2477. J. A. Turner. Paper.

2490. A. V. Newton. Cooling fluids. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the Gazette in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Nov. 11, 1859.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

WRIGHT-IRON GIRDELS, Calcutta and South Eastern Railway.—For the ironwork required for a bridge of 128 feet 6 inches clear span for carrying the railway over Tolly's Canal, Calcutta. Copies of the plans and specifications price £3 3s. per set at office, Mr. Longridge, 18 Abingdon-street, Westminster. Tenders, 211 Gresham-house, Old Broad-street, London, Nov. 25, at noon.

RAILWAY ERECTIONS, Scotland.—For a timber station-house and goods shed for the Daily station of the Maybole and Girvan Railway; also a stone-built goods shed at Maybole station. Plans and specifications at the secretary's office, Girvan. Further information of the engineer, Mr. J. Miller, 25 Northumberland-street, Edinburgh. Tenders with the secretary, Mr. J. Macdonald, Girvan, Nov. 25.

RAILWAY STATION.—For the erection of the Kirby Stephen Junction station on the South Durham and Lancashire Union and Eden Valley Railway. Plans, &c., railway office, Barnard Castle. Tenders, Nov. 20.

COVERED PIER ROAD, Scotland.—For construction of a covered passage between the station and pier at Burntisland. Plans and specifications, the secretary of the Edinburgh, Perth, and Dundee Railway, with whom tenders, Nov. 24.

RESERVOIR, West Melton.—For a service reservoir, &c., and laying earthenware and cast-iron pipes for the supply of water to West Melton and portion of Wath. Drawings and specifications, Waterworks Company's Office, West Melton, and at the office of Mr. J. M. Land-borough, C.E., 23 and 24 Queensgate, Bradford. Tenders to the Rev. J. Boyd, West Melton, Nov. 24th.

MACHINERY OF A FLOUR-MILL, Scotland.—According to plans and specifications with Mr. D. Chalmers, flour-miller, Dicksfield, flour-mill, Arbroath, to whom tenders Nov. 22.

SEWERING, Enfield.—For laying glazed pipes and forming certain tanks with a brick sewer at Ponder's End, and other sewage works. Plans and specifications, Mr. Beardmore, 30 Great George-street, Westminster, when bills of quantities will be supplied on payment of 10s. Tenders to Local Board of Health, Enfield. Nov. 24.

ASYLUM, Rainhill, near Prescot, Lancashire.—For certain alterations and additions to the County Asylum, Rainhill. Plans, office of Mr. H. P. Horner, 10 Becket-street, Liverpool. Bills of quantities, Mr. J. Longrigg, Lord St., Liverpool. Tenders to Mr. T. Martin, at the Asylum, 21st Nov.

SCHOOL, Eastleach Turville and Eastleach Martin, Gloucestershire.—For the erection of a joint school and teacher's residence. Specifications, offices of Messrs. G. and P. W. Fowler, Eastleach Turville.

HOUSE, Headingley.—For the masons', bricklayers', joiners', and carpenters', plumbers', plasterers', slaters', and painters' work required in the erection of a villa residence, with stables, coach-house, &c., to be built at Headingley. Plans, &c., office of Mr. T. Shaw, architect, 2 Belgrave-square, Leeds. Tenders to Nov. 24.

TAR, &c., Walsall.—For the tar and ammoniacal liquor made at the Gas Works, Walsall, for three years, from January 1st, 1860. Tenders, which stating price per ton of 210 gallons for tar, and also the price per 1,000 gallons for ammoniacal liquor, must be sent to the Commissioners' Clerks' office, Bridge-street, Walsall, Nov. 28.

CONVEYANCE OF TIMBER.—For the conveyance from Dune Forest to Pembroke Dockyard of about 340 ends of oak timber, containing about 470 loads, and from High-Meadow Woods of about 164 ends of ditto, containing about 255 loads. Tenders, Dec. 1, to Mr. J. Campbell, Deputy Surveyor of Dean Forest and High Meadow Woods, Whitmead Park, Colford, where the form of contract may be seen, and further particulars obtained.

MANAGER.—An active, experienced man as foreman or manager of an agricultural machine-making and engineering work in Forfarshire. Applications, stating age, qualifications, and expected salary, No. 234, North British Advertiser Office, Edinburgh.

WATER-WORKS SUPERINTENDENT.—A man of intelligence and experience in water-works to proceed to St. John's, Newfoundland, about 1st April next, to superintend the operations of bringing into the town of St. John's a supply of water. The party applying must produce testimonials from competent engineers of his ability to carry out a plan of the proposed works, which are extensive, and to be able to construct embankments, the laying of pipes, &c. An engagement of two years will be given. Salary, £300 and free passage out. If the party gives satisfaction, may be continued in charge of the works. Apply to J. R. Forman, Esq., engineer of the works, 156, West George-street, Glasgow; or to Messrs. Baine and Johnston, Greenock.

MACHINIST.—A practical machinist, who thoroughly understands the management of newspaper printing machines. Apply by letter to the proprietor of the Irish Times, 4 Lower Abbey-street, Dublin.

FOREMAN OR MANAGER, Engineer's Factory.—Must be perfectly acquainted with every description of steam and general machinery, foundry and smiths' work, boiler making, &c. Full particulars, age, salary, &c., to S. M. F., Southampton.

WORKING FOREMAN in an Engineer's Factory.—Must be a good practical turner, fitter, and erector. Messrs. G. Thompson and Sons, engineers, Eccleston-street, East, Finsbury.

CONTRACTOR'S PLANT TO BE SOLD, Scotland.—By private treaty at Silloth Dock, near Carlisle. Two twenty-horse high pressure horizontal steam-engines, with radii, &c., complete; makers, Cowans, Sheldon and Co., Carlisle. Two sets of winding drums, driving gear, &c., complete, suitable for working inclines, or for colliery purposes. One locomotive engine and tender; maker, Hawthorn, Newcastle. One donkey engine for pile driving. Application to Mr. Nelson, contractor, Carlisle; or to Mr. Middleton, on the works, Silloth Dock.

PRICES CURRENT OF METALS.

London, Nov. 18th, 1859.

LAWRIE AND HAGGER, Metal Brokers

33 Lombard-street, E.C.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 25, 1856.

THE EDUCATION OF NAVAL
ARCHITECTS.

THERE is this unfortunate circumstance connected with education of every kind, viz., that it cannot be properly understood or valued by those who do not possess it. This is particularly true of professional education—probably more so in reference to naval architecture than in any other instance; and it is unquestionably the cause of that strange jealousy between educated and uneducated shipbuilders which is known to exist throughout the country. The gulf between the few thoroughly educated men and all the others is so great—owing to the comprehensiveness of the studies which the real naval architect must master—that we do not wonder at the want of harmony between the two classes.

The good old "practical" shipwrights (as all those who are utterly ignorant of mechanical principles are especially fond of calling themselves) are both a very wide-spread and a very self-satisfied race. Outside of Her Majesty's service there are exceedingly few shipbuilders who do not belong to this class; (and we are now alluding, let it be understood, to builders of wooden ships, and not to the many boiler-makers who have of late years set up in what is called the iron-shipbuilding line;) while within the Government service there is by no means any superabundance of persons who may fairly be ranked as masters of their profession. We do not for a moment desire to detract from the merits of good practical shipwrights. All the time they confine themselves to the duties for which they are competent—those of converting, shaping, and combining materials, and of conducting general shipwrights' work—we value them as highly, probably, as they value themselves. Much depends upon them, both in the public and in private service, and no sensible man would ever slight either their abilities or their services. But, unhappily, such men often make the mistake of feeling and speaking with contempt of accomplishments which, to say the least, are as valuable as their own; and not unfrequently they are further guilty of losing sight altogether of their own deficiencies. Often and often have we come into contact with men who could not write a sentence of their own language intelligibly, or even speak one correctly, or tell a square-root sign from an Assyrian hieroglyph, or measure the stability of a ship any more than they could predict the place of the planet Neptune, and who nevertheless have spoken with the coolest contempt of those higher acquirements of which they cannot possibly form the faintest conception. Now, while we esteem these men as practical shipwrights, we should like them to understand that their ignorance and presumption are very reprehensible.

Many of the mistakes which are made on this subject spring from the foolish belief that the possession of a theoretical knowledge of naval architecture cannot co-exist with good practical abilities. But the fact is, the two things are perfectly compatible, provided only that sufficient time for the acquisition of both be allowed. A man may speak and write English and yet be a shipwright; he may be able to solve an algebraic equation, and have mastered the books of Euclid, and yet be a shipwright; he may even have so far made himself an accomplished mathematician as to be able to deal with the difficult questions which the true

naval architect must comprehend, and yet be a shipwright. No man can, of course, do all this in a year, or in seven years; but if theoretical studies and practical shipbuilding experience be properly blended, there is no conceivable reason why men may not in due time become masters of both branches of their profession.

In the private service, unhappily, the theory of shipbuilding, or naval architecture, has been all but utterly neglected of late years. The "rule of thumb" has been the golden rule, and we should scarcely know to what private shipbuilders to turn for anything beyond it. And wooden-shipbuilders are now paying the penalty of their neglect. They have been content with so small a measure of scientific skill on the part of themselves and their shipbuilding officers, that as we have already intimated, mere boiler-makers have no hesitation in entering into open competition with them. Nor is their competition vain; on the contrary, the builders of wooden ships are rapidly falling behind in the race, and if they do not stir themselves while it is yet time, the iron-shipbuilders will beat them almost altogether from the field.

It may be well before proceeding further with these remarks to draw the attention of our readers to the views of one of the so-called "practical" shipwrights on the question now under our consideration. Mr. John Edye, C.B., F.R.S., late First Assistant to the Surveyor of the Navy, is one of this class of persons—a man who always seemed to us and others to have a natural contempt for science, courtesy, the Queen's English, and many other things that men of cultivated minds are liable to esteem; and in his evidence before the Dockyard Committee of Economy he has favoured us with his opinions. He says:—"I am of opinion that 'the system of education in the dockyards only tends to disqualify the workman for his practical duty, in many cases. I do not object to education; I am a great advocate for it; but it appears that by the present system, a number of these young men, educated in the manner they are, are dissatisfied with their situations, and in after life become discontented with their positions, but being burthened with young families, that is their only tie to the service; those who are not so leave to better themselves; so that Government has not benefitted by the good intention. And as these young men have the preference of advancement over the practical workman, the latter becomes dissatisfied with the mortification he is placed in by the control of the educated youth, who is greatly deficient in his practical duties (which experience alone can be obtained by long servitude), consequently the service suffers. In all great establishments in the river, both shipwrighting and engineering, the duties are conducted by experienced, practical workmen; and I believe, further, that you will not find in any of the establishments of shipwrighting or engineering that the practical detail of the establishments is conducted by theorists; as it is very evident the practical man can conduct his duties with the workmen, when the theorist only causes confusion and embarrassment, which ends in perplexity and loss of property, from the want of proper control, by the inability of the inexperienced."

We have quoted Mr. John Edye's language, exactly as it stands, in order that the luminous character of his ideas may be fully presented to the reader; and, having done so, we would ask where in the wide world could we look for a more striking proof of the necessity of education than these remarks of Mr. Edye's afford? Here we have a man who has held for many years the highest professional post in the ser-

vice, and who is now sweetening his later life with a handsome pension, coming before a committee with trash like this!—telling us that certain men are "dissatisfied with the mortification" they are "placed in"; talking of "confusion and embarrassment which ends in perplexity," and so forth. We might surely object to such a man offering any opinion whatever upon the subject of education. But, waiving our right in this respect, let us look for a moment at what he says. The words "I do not object to education; I am a great advocate for it," must be passed by as simply meaningless, or, at the best, as a concession to other people's better sense. He is opposed, he says, to the "present system" of education in the dockyards. But what does he mean by this? He cannot, of course, refer to the systems under which the members of the School of Naval Architecture, or those of the more recent School of Mathematics and Naval Construction were trained, because these systems no longer exist. It would appear, therefore, that Mr. Edye must mean the present dockyard school system; and, if so, it is manifest that he is opposed (whatever he may say to the contrary) to education itself, for no system can be simpler or more harmless than that in question. Mr. Edye has been pottering at Somerset House and Whitehall for so many years past, at a post to which he was raised by a man who understood but little more of naval construction than he himself, that he can have had but little or no immediate acquaintance with the working of the dockyard schools. Let us turn then to what is said of them by those who have had the system immediately under their eyes. And first we find Mr. Abethell, the present Master Shipwright of Portsmouth Dockyard, bearing very different testimony. He thinks the schools have had a beneficial influence on the young workmen, and does not consider that any too much time is spent in them by the apprentices. Again, Mr. Moody, Assistant to the Master Shipwright at Portsmouth, thinks the young men who come out of their time now in the Government Dockyards quite equal as shipwrights to the men from the private service, and better in respect of discipline. And, without going further, even Mr. William Edye, the brother of our first witness, and who was the Master Shipwright of Devonport Dockyard for fifteen years, thinks the dockyard school system "a very good system." It is in opposition to abundant evidence of this kind that Mr. John Edye presumptuously falls foul of the simple and effectual means of education which is offered to the apprentices of Her Majesty's Dockyards, and, in fact, of education itself. Were we to give such men as he their way, in respect not of shipbuilding only, but of all other mechanical arts, how long would England be ere she had to dip her flag to every trumpery foreigner? Let us have a better reason for putting a stop to education than Mr. Edye's, viz., that the ignorant get "dissatisfied with their mortification."

There is one fact to which Mr. John Edye refers, and which is often observed by other people, that cuts two ways. They tell us that young men trained in the Government service frequently leave it to better their positions; and this is doubtless the case. But why is it so? First, because the Admiralty are disgracefully backward in rewarding their best men; and, secondly, because private shipbuilders train exceedingly few clever men of their own. To the latter circumstance we have already referred. Private shipbuilders have done next to nothing in the way of cultivating their young men in the science of a profession which requires more study than any other. In the engineering trade the necessity of a careful

and extended training in mathematical and physical science is well understood; but what shipbuilders know or care anything of such subjects, or seek to impart a knowledge of them to their people?

On the other hand the Admiralty have yet to make great changes in their modes of dealing with their trained servants. They have in their service the most skilful and educated naval architects in the world, but what have they yet done to distinguish or reward them?—what are they even now doing in recognition of their services? In their office at Whitehall, for example, they have several men of the very highest culture and ability, who are daily performing duties for which nothing but great natural endowments and prolonged studies could have qualified them—men whose superiors are certainly not to be found elsewhere. Yet they are content to write these gentlemen down Mr. — in the Navy List, to call them "Draughtsmen," and to give them very low salaries; while in the very same offices men of the most moderate abilities and the plainest education are dubbed Esquires, designated "Clerks," and have liberal salaries bestowed on them! And in the dockyards matters are no better. Some of the young men who were trained at the late School of Mathematics and Naval Construction have been shamefully neglected, not to say obstructed, by the officers of the Admiralty; and more than one of them who are men of good ability are at the present moment, after seven or eight years of service, anxiously looking for inspectors' appointments at £125 a-year! Such a state of things is discreditably in this country, and the Admiralty cannot mend it too soon. In the private service far inferior men are in receipt of salaries treble and fourfold greater than those which the Government give to some of their best servants.

AUXILIARY STEAM POWER IN MERCHANT SHIPS.

OUR respected correspondent, Mr. Cunningham, R.N., the inventor of the method of reefing square sails which bears his name, has addressed us a letter, which will be found in another column, on the employment of auxiliary steam power in the merchant marine. Mr. Cunningham's remarks apply especially, indeed we may say exclusively, to the Australian voyage, and his view of the matter is, that the advantages of applying an auxiliary screw to vessels making that voyage have not yet been satisfactorily demonstrated. The subject is a very broad one, and we notice it here without the least expectation or intention of dealing with it either fully or finally; for to do this we should require more numerous and comprehensive data than we happen to have before us. But there are a few facts which may be mentioned at once with advantage.

And in the first place we would remark that our position in reference to the question is less that of an advocate of the auxiliary screw than that of one averse to a too hasty condemnation of it. In our article on the Royal Charter, we simply argued that the loss of the ship in no way proved the screw propeller "baneful," and that, on the contrary, that instrument had really proved of great advantage to her on her very first voyage; while in the foot-note which has occasioned Mr. Cunningham's letter we merely dissented from the conclusion that it was "questionable whether any advantage has been obtained at all" by the use of the screw. This being our attitude—one of simple resistance to a too hasty condemnation of the auxiliary screw—we are at a loss to see that Mr. Cunningham has in the least degree made our

ground untenable by his present letter. If the screw is to be utterly rejected from Australian vessels let us have the reasons for its rejection clearly set forth. Mr. Cunningham's statements amount to no more than mere *suspensions* of its inutility.

We said in our former article, on Dr. Scoresby's authority, that the Royal Charter overtook a vessel on her first homeward voyage, "and found that her own steam power had enabled her to gain 4,000 miles upon the other vessel in forty days." To this Mr. Cunningham refers, but only for the purpose of slurring the fact over. Now, we think it is a fact which should not be slighted; a gain of 4,000 miles in forty days is an advantage which must possess great weight in the determination of the question now before us. On again referring to Dr. Scoresby's Journal, and glancing roughly through it, we find that the steam power was applied to the Royal Charter on at least fourteen occasions during her first voyage to Melbourne, for intervals varying from half-a-dozen hours to as many days; and that on her homeward voyage it was employed no less often—once for fourteen days at a stretch. It will be seen from this that when Mr. Cunningham mentions "eight days" as a possible gain he gives the screw credit for far too little. If he had said from fifteen to twenty days he would have been nearer the truth, in so far as the Royal Charter's voyage is concerned. Nor is hers an unexampled case. We have before us the fact that the Kent, a ship which left Melbourne on the 1st of March, 1855, made a splendid run round the Horn and northward to the Equator in 40 days only, but was then kept almost in the same place by light winds and calms for no less than 17 days, during which long period she "accomplished almost nothing." And there is but little doubt that like facts might be accumulated in abundance. We have not, as Mr. Cunningham implies, advanced the rapidity of the Royal Charter's voyage "as a conclusive argument" against his former remarks; but we nevertheless consider that the record of that voyage affords great reason for doubting the correctness of his view of the matter.

At the same time we are quite willing to admit—nay, are anxious to have it understood—that the Cunningham system of reefing sails does, as our correspondent contends, offer great facilities for shortening voyages. With the old system of shortening sail it is most dangerous to carry on a press of sail at times when with the Cunningham system it is perfectly safe to do so. Dr. Scoresby's journal, upon which we have already drawn for so many illustrations, indirectly throws some light on this point also. The Royal Charter was fitted with the American (Captain Howe's) system of double topsails on each mast. In this system the lower topsails are similar to close-reefed sails, but have their yards fixed to the lower mast heads, so as merely to traverse by the braces like the lower yards. The upper topsails, comprising one reef, are hoisted up by the yards in the usual way, and if required to be taken in suddenly, they may be dropped down before the lower sails, without requiring any further immediate attention. This plan is manifestly greatly inferior to Mr. Cunningham's; but at the same time it affords considerable advantage. Dr. Scoresby speaks of it very highly. In reference to a gale which occurred on the outward voyage, he says:—"In this gale we experienced the special advantage of the double topsails enabling us, by the strengthening of two yards, to carry them both throughout the night, and relieving the men from labour and the ship from loss of time and speed, by requiring, in almost the

"heaviest weather, no reefing. All that is generally needful when, as in their present condition, the foot of the upper topsail is laced to the head of the lower one, is to lower the upper yard down, and leave the topsail to lie in the calm of the other sail, quietly before it." In another place he speaks of these sails as "avoiding the necessity of reefing by the mere lowering down of the upper sails; and so, whilst saving the labour of a large number of men, enabling the navigator to carry sail fearlessly, even in the contemplation of bad weather, from the facility afforded him of reducing, almost by self-acting arrangements, his topsails into their smallest dimensions." He also quotes special instances in which the facility of shortening sail was made actually available in time of exigency. We have only to add, on this part of the subject, that what Dr. Scoresby here says of the American system has been said a thousand times, and with far greater earnestness and urgency, of the Cunningham system, the author of which has in no way exaggerated its merits.

Mr. Cunningham is quite right in reminding our readers that his plans are as applicable to, and as useful in, screw vessels as sailing vessels, wherever, as is usually the case, the screw is but an auxiliary aid to the vessel's progress. We should like to see it at once adopted in all the light vessels (at least) of the Royal Navy, in which activity and efficiency are of the highest moment. We have some hope of seeing this accomplished.

As to Mr. Cunningham's concluding suggestion, respecting the application of steam power to the working of ships' sails and anchors, we need hardly say we shall at all times show ourselves favourable to every well-considered plan having this for its object.

THE COMPASSES OF IRON SHIPS.

THERE are few subjects of greater practical interest than that of the deviation of the compass in iron ships. In wooden ships the compass was erratic enough, and at the very beginning of the present century its variable nature engaged the attention of Captain Flinders, on his Australian voyages. This intelligent officer discovered many important facts connected with the question, and devised formulæ and modes of correction which are still applicable. He observed that the trouble of correction may be saved if a place can be found near the taffrail where the attraction of the iron at the stern will counteract by its greater vicinity the more powerful attraction of the centre and fore parts of the ship, and that should the attraction be too weak, it may be increased by fixing one or more upright stanchions or bars of iron in the stern. He further says, if a neutral station can be found or made exactly amidships, and of a convenient height for taking azimuths and bearings, let a stand be there set up for a compass; and if the stand must of necessity be moveable, make permanent marks that the exact place and elevation may always be known. Observations taken there should never undergo any change from altering the direction of the ship's head at any dip of the needle, but it will be proper to verify occasionally, and to compare azimuths and bearings with others taken on the binnacle. The course should also be marked by this compass, though the ship be steered by one before the wheel, a quarter or half point being allowed to the right or left according as the two may be found to differ. Mr. Archibald Smith, in his recent introduction to Dr. Scoresby's journal of a voyage to Australia, states that little can be added even at the present day to Captain Flinders' observations in regard to wooden ships. We may here add that Mr.

Smith, in the introduction just mentioned, gives a summary of the proceedings which have from time to time been taken in order to clear up the whole question of compass deviation and correction, and the controversies which have arisen respecting it—controversies which, particularly in the case of that which was sustained by the Astronomer Royal on the one side and Dr. Scoresby on the other, have led to very useful results.

About 1840 a committee of scientific men and naval officers appointed by the Admiralty recommended the form of compass now used as the standard compass in the navy, and the correction of the deviation, not by mechanical corrections, but by "swinging" the ship, and obtaining a table of deviations to be afterwards applied to correct the observed courses and bearings. This system has ever since been successfully followed in Her Majesty's ships, under the superintendence first of Captain E. J. Johnson, R.N., and subsequently of Mr. F. J. Evans, Master, R.N., whose valuable paper on magnetism was published in the *MECHANICS' MAGAZINE* for July 15 and 22, 1859. The success of this method has indeed been so great that there is reason to believe no vessel belonging to the Royal Navy has been lost through the inaccuracy of her compasses since the Birkenhead's disaster. But in the mercantile marine the case is very different, since no uniform system has there obtained. "The profession of a compass-adjuster," as Mr. Archibald Smith truly says, "has sprung up. Each compass-adjuster corrects in his own way. The merchant captain does not understand the process. He assumes that his compasses are correct till he finds out that they are in error, sometimes by shipwreck; and when he discovers the error at sea he is unable to correct it himself, and is obliged to navigate disregarding the compass." In 1854, however, was appointed the Liverpool Compass Committee, consisting of Thomas Brocklebank, Esq., merchant and shipowner, Chairman; J. P. Palmer, Esq., shipowner, Deputy-Chairman; Thomas Court, Esq., Secretary of the Underwriters' Association, Treasurer; John Grantham, Esq., naval architect and consulting engineer, and John T. Towson, Esq., Secretary of Local Marine Board, Honorary Secretaries; Mr. W. W. Rundell, Secretary; some score or more of gentlemen appointed by the Shipowners, the Underwriters, and the Steam-ship Associations, and by the Literary and Philosophical and the Polytechnic Societies; and the following gentlemen, whose names were added by the General Committee, viz., Commander Bevis, R.N., Agent for Transports; E. Heath, Esq., President of the Chamber of Commerce; John Laird, Esq., iron-shipbuilder; Joseph Mondell, Esq., shipowner; W. Potter, Esq., Chairman of the Underwriters' Association; and Capt. Schomberg, R.N., the Chief Emigration Agent of the port. The names of Professor Airy, F.R.S., Astronomer Royal; F. J. Evans, Esq., R.N.; Rear-Admiral Fitzroy, F.R.S.; Major-General Sabine, R.A.; Dr. Scoresby; and Archibald Smith, Esq., M.A., F.R.S., were afterwards added to those of Honorary Members. This Committee was appointed to investigate the causes of the deviation of the compass in wooden and iron ships, and to ascertain the best means of correcting errors arising from this source, especially in iron ships; and has certainly prosecuted its inquiries with considerable zeal and success. Its first and second Reports have for some time been before the public, but have not hitherto gained all the attention which they deserve. Our present object is mainly to give them—the latter in particular—that increased publicity which they

well deserve. In doing this we shall, for the sake of convenience and accuracy, adhere as closely as possible to the language of the Committee.*

At an early date it became apparent to the Committee that in pursuing their inquiries, besides the difficulties belonging to the subject, they would have to overcome the apathy of shipowners and the inertia or active opposition of persons interested in maintaining things as they are. Even when merchants and shipowners were willing to accede to the wishes of the Committee, they were met by the heavy expense and delays attendant on experimenting upon and moving such ponderous masses as iron ships. To these must be added impediments arising from frequent changes in ships' steering apparatus, and the position of the binnacle; from new fittings and the varying quantity and stowage of the iron in a ship's cargo; the proximity of other iron ships on the building slip, or by the wharf; and numerous other retarding or vitiating accidents which will readily suggest themselves to persons conversant with maritime affairs. In some cases there was reason to suppose that information forwarded to them was not to be depended upon; that with compass deviations arising from the iron of the ship, they were favoured with others due to personal and accidental causes, imperfect instruments, local attraction on the shore compass, and a bad system of "swinging." The returns made to the Committee, and really available for the inquiry, where by such causes so much reduced that it is chiefly by the co-operation of a comparatively small number of captains, and the strenuous exertions of the Committee, that any progress has been made. It is, however, believed that the Report contains valuable and trustworthy information respecting the direction and amount of what is now generally termed a ship's sub-permanent or retentive magnetism, and the fluctuations to which the more changing part of her magnetism is subject. That part of the inquiry which depends on observations made in other latitudes is for the most part reserved for the next Report, when the data in the possession of the Committee will be much increased.

Many of the difficulties and hindrances which have been alluded to were overcome by the introduction of a complete system of magnetic bearings, painted by request of the Committee upon the dock walls of the port of Liverpool, and the use in conjunction with these of a gimballed "dumb card." The pointed bearings, besides affording the captain of every ship which enters or leaves the docks or swings with the tide in the Mersey, the means of testing the accuracy of his compasses, have enabled the Committee to gather much important information which would otherwise have been quite unattainable. They have proved, too, most decisively that the deviations of the compass on board iron ships, when properly ascertained, are not of that irregular and erratic character which many cards of deviation might lead one to suppose, but that they accord most closely with the deductions of theory and experiment, as exemplified in the works of the Astronomer Royal and Mr. Archibald Smith. The Committee have been practically convinced that a good deviation table, when projected by Napier's or any similar method, assumes so simple, regular, and intelligible a form, that the practised eye can at once decide upon the degree of confidence it should command, and

* Those readers who are not fairly acquainted with the laws of magnetism would do well, before attempting to study the remaining portion of the above article, to read the exposition of magnetical principles with which Dr. Scoresby has prefaced the volume which we reviewed two or three weeks since.

on the general distribution of the ship's magnetism at the place of the compass to which the table belongs.

The records of the Committee no longer allow a doubt as to the connection which exists (and upon which Dr. Scoresby so long insisted) between the direction of a ship's original magnetism and her position when upon the building slip. In all the ships which have been examined, the north end of the compass needle invariably deviated towards that part of the ship which was furthest from the north while she was building, if the compass was placed in a central position and free from the influence of individual masses of iron. When this is admitted, the following question is immediately suggested: Of ships built in various positions, which have the smallest deviating action on the compass? To answer this satisfactorily, it is necessary to consider not only the amount but the permanence of this action; to refer to experience gained in long as well as short voyages; and to free the observations from the influence of bulk-heads, pumps, rudder-head, and stern-post, or proximity to other individual masses of iron. This involves an amount of labour and research which few persons besides those who have attended to the subject will be able to appreciate. Before concluding their investigation the Committee hope to be able to give the question a practical answer.

The original magnetism of a ship, by which is meant that dependent on her direction when building, as it forms a leading characteristic, is first treated of by the Committee. In amount it appears to have close relation to the size of the ship or the quantity of iron used in her construction. In a ship of 400 tons, built head to east, where the deviation of the compass is always toward the starboard side, if a compass be carried fore and aft on the middle line, about three or four feet from the deck, the deviation may be ten or twelve degrees when her head is north or south. In a ship of 1,000 tons, it may under the same conditions be 25° or 30°, or more, depending to some extent on the breadth of the ship. This deviation of the compass to starboard in ships built with head to east, and to port in ships built head to west, must be remembered to be caused by a differential action only. Both sides of such ships (in north magnetic latitudes) attract the north end of the compass needle, as will be seen by approaching either side with a compass, either internally or externally. One side, however, attracts the needle more strongly than the other; and this is the side which was furthest from the north when the ship was building. In discussing observations made in opposite hemispheres, and in considering the effect of heeling, it is important to remember this. If these ships be turned with head to east or west, the north end of the needle will tend to the bow or stern respectively, according to the direction in which lies the greater mass of iron, except when influenced by bulk-heads, or proximity to bow or stern—the stern especially, as here the stern-post, rudder-head, and other masses of vertical iron will control the attraction of the remainder of the ship.

In a ship built head to north, or near it, there will be no apparent attraction of the needle towards the sides while she lies in a N. or S. direction. In all other directions a strong attraction towards the stern will be noticed, except the needle be carried very near to the bow or the aft side of a water-tight compartment, when the contrary action may be seen. At a considerable distance from the stern in such vessels the deviation may amount to 40°, and at three or four feet from the rudder-head to 100, 150, or even 180 degrees. In ships built head to east, where the attraction etc.

not nearly so strong, the deviation of a compass placed near the rudder-head, &c., will approximate to these amounts. In one such instance the error in the first position of the binnacle was 101° . As the ship was going to the East Indies, the compass-adjuster objected to compensate so large an amount, and the binnacle was then placed three feet forward; here the error was reduced to two points. In another and much larger ship (the Dreadnought), the compass in the first position of the binnacle deviated 14 points; on moving it a little further forward, the error was reduced to $2\frac{1}{2}$ points. To ships built head to south the same principles will apply. The deviation is chiefly towards the bow. Usually in these ships there is a space near the stern where the attractions are so nearly balanced that frequently no compensation of the steering compass is attempted; yet elevated compasses placed aft in the same ships will show considerable deviation, the errors increasing for some distance as the compass is carried aloft.

The prominent characteristics of ships built with head towards the cardinal points have now been described. In ships built in intermediate positions these characteristics will be combined. Thus, in ships built head to N.E. the attraction will be aft and to starboard; head to N.W., aft and to port. If the head be S.E. or S.W., the deviation will be forward and to starboard, or forward and to port respectively. But it must not be hastily concluded that those positions for building which give the smallest errors aft are to be preferred. The choice must depend on many other considerations. Ultimate permanence of deviation under change of geographical position is a quality to be more highly valued.

The original magnetism of an iron ship is frequently very permanent as regards direction, but is believed to undergo rapid changes in its amount, both in reality and in its apparent effect on the compass; the most striking change being at and immediately after launching, and during the first voyage. It is usually more evident in a steamer than in a sailing vessel. There are cases in which the deviations in a steamer have changed so much as two points in the first two days at sea, while afterwards the change has not been more than three degrees in as many months. The deviation of the Great Eastern's compass as she lay at Portland amounted to about twice as much as it was found to be subsequently at Holyhead—showing that her voyage between the two ports shook out of her a considerable portion of the magnetism which the iron hull exerted upon the compass. A change took place to a considerable amount (not far from two points!)—a fact which tends to strengthen our confidence in the practice adopted in the Royal Navy of finding the deviation at every opportunity. In new sailing ships the change is generally, but not always, more gradual, and extends over a longer period. A change of 10 to 15 degrees is not unfrequent. In proof of this may be quoted the general testimony of compass-adjusters. Each time a ship is re-swung, the compensating magnets are usually placed at a greater distance from the binnacle, or one or more are taken away altogether. In such instances there can be no doubt as to a reduction of the ship's magnetism having taken place. In the comparatively few cases in which compensating magnets have been added or placed nearer to the binnacle, the contrary inference is not so certain. The magnets may have lost their power more rapidly than the ship hers, or the ship's force in one direction may have been unmasked by a more rapid change in another, examples of which are on record.

Under some circumstances considerably more than one-half of a ship's original magnetism, or rather that part of it which affects the compass, may be lost, or may become balanced in the course of a year. Of this the Royal Charter is an example, as the following letter from the Astronomer Royal will show:—

Royal Observatory, Greenwich, Oct. 2, 1859.

MY DEAR SIR,—Business of the Observatory has prevented me for some time from examining the observations of the deviations of the standard compass in the Royal Charter, which you were so kind as to send me. I have, however, now taken them up, and find the following results:—

1. Quadrantal deviation.

Liverpool, 1858, January	+ $6^{\circ} 40'$
Melbourne, " May	$5^{\circ} 50'$
Liverpool, " August	$5^{\circ} 51'$

These agree well with each other, and with the values which you had deduced. Their magnitude shows that the use of a mass of soft iron, to produce correction of the quadrantal deviation by its transient induced magnetism, must never be neglected. In this instance it would have left an uncertainty of 12° . I fear persons who correct compasses have been too much in the habit of omitting this.

2. Ship's sub-permanent magnetism towards the head (estimated in absolute measure in Gauss' manner, the units of measure and weight being the English foot and English grain). Whole horizontal force of terrestrial magnetism at Liverpool = 3.64 ; at Melbourne = 5.84 .

Liverpool, 1858, January	— 0.199
Melbourne " May	— 0.147
Liverpool " June	— 0.108

3. Ship's sub-permanent magnetism towards the starboard side, similarly estimated:—

Liverpool, 1858, January	— 1.158
Melbourne " May	— 0.895
Liverpool " August	— 0.208

The value of these numbers will perhaps be best understood by remarking that at Liverpool a deviation of 1° will be produced by $.062$ in either of these magnetisms; at Melbourne a deviation of 1° will be produced by $.104$.

It appears, therefore, that the ship's magnetism (sub-permanent) has diminished in both parts of the voyage. The fore and aft magnetism has diminished very uniformly; the transversal magnetism has diminished more in the second or homeward part of the voyage than in the first or outward part.

Perhaps you may think fit to communicate this, with my best wishes for their success, to the Liverpool Compass Committee.

I am, &c.,

G. B. AIRY.

In support of the fact, the following are taken from a number of examples to the same effect which have been collected by the Compass Committee:—(1.) The *Panic* iron sailing-ship, built head to east; one of the oldest sailing iron-built ships in the port. It is stated that each time this ship has been swung the magnets were found to be too strong. When swung in 1856, after her return from the East Indies (to which she has made several voyages), one compensating magnet, a transverse one, was removed entirely; the fore and aft magnet was placed at a greater distance from the binnacle. (2.) The *Sarah Palmer* iron sailing-ship, built head E. by N. On the building slip at Warrington the attractions balanced each other between five and six feet from the rudder-head. A few days after launching, at Liverpool, head nearly in the same position, the balance did not take place till the compass was placed more than twenty feet further forward. Of a number of observations made on the deck-house, near the centre of this vessel, and similar observations made a few days afterwards, the ship's head being within 8° of the same direction, the average reduction of the deviations was from 37° to 11° . Making a liberal allowance for the small difference in the direction of ship's head, the change may be taken as from 3 to 1. (3.) The *Astrea* three-masted sailing-schooner, built head to south and west, was adjusted in the Clyde, and a table of residual deviations

given. She sailed to the West Indies, and the deviations corresponded with the table. On the home voyage the Captain observed a change of nearly two points, and before he met with any bad weather. The difference was shown to be due to a reduction of the ship's magnetism by taking away the compensating magnet. There being no time allowed for re-adjustment, the magnet was again put in place, and she sailed to the Mauritius with deviation table, this being considered sufficient precaution for "clearing" the Irish Channel and getting sea room. Recent letters show that she experienced still greater changes in going south. (4.) The *Nau-phante* iron sailing-barque, built head east. Fore and aft and transverse magnetisms decreased after launching. (5.) The *Boetia* S.S., built head south and west, was swung, adjusted, and table of residual deviations given to the Captain, who re-swung her immediately after, and before sailing from the east coast round to Liverpool. Before reaching the English Channel, the steering compass was discovered to be two points out, and the same amount of deviation was also observed by the pilot on bringing her into Liverpool.

The following easy mode of testing the fact which these cases illustrate is given by the Committee. It has frequently been adopted when no other presented itself, and is almost universally applicable. With a small pocket compass ascertain the direction of the north poles of the compensating magnets. This will indicate pretty correctly the direction of the ship's original magnetism. Observe the direction of ship's head, and whether any deviation exists. Cases in which sufficient deviation for this test is not to be found are extremely rare. It will be seen that the deviation is in the direction contrary to that which would be caused by the ship's magnetism, and is therefore due to the magnets being too strong. When the compensation is partly effected by chain-boxes, there can be no uncertainty on this point; in other cases the result may appear equivocal, unless the effect of horizontal induction be considered.

The Committee next inquire what would be the effect of such reduction of the transverse magnetism in ships built with head easterly, as is the case with so many vessels belonging to the port of Liverpool. It is evident that the north end of the needle of an adjusted compass will be repelled from the starboard side, giving east deviation on southerly, and west deviation on northerly courses. Further, if the reduction of the transverse magnetism forward from the binnacle affected the balance of the fore-and-aft attraction, the attraction of the needle towards the stern would be relatively increased, and there would also be east deviation on westerly, and west deviation on easterly courses. Thus, these vessels, whether on southerly or westerly courses, and particularly on southerly and westerly courses, would tend to the right of their course. That these ships do so is well known. To quote only one, though another and most painful instance will also suggest itself:—Captain Heron, of the *Mystery*, built at Warrington, head E. by N., states that after leaving Liverpool, with compasses adjusted, on her first voyage, he shaped a course for the Smalls, and kept to it. He found, however, that it took him so much to the right of his apparent course, that he considers he must have been about mid-Channel. Had he set a course for the Tusker, or even for mid-Channel, instead of one near the Welsh coast, the consequences might have been serious. From what has already been stated, it will be inferred that the larger the ship the greater will be the amount of change, and so much the more to the

right of her course, under the same circumstances, would such a vessel be taken.*

After this early reduction of a ship's magnetism has taken place, the remaining portion, as far as may be judged from examinations made in the same place and under the same circumstances, appears to be comparatively permanent. The most striking case that can be quoted is, perhaps, that of the Great Britain. This extraordinary ship has been stranded, and strained, and altered; has traversed both hemispheres, and been very many years in active service; yet her lines of no deviation are now much the same as Dr. Scoresby would indicate them to have been when she was upon the stocks. The Great Britain also shows what has so frequently been insisted upon by Dr. Scoresby, that the tendency of these lines, with the lapse of time, is to approach the horizontal direction; but, except towards the middle of the vessel, little more than a tendency to it.

CAPTAIN BLAKELY AND THE ARMSTRONG GUN.

In another column we publish a challenge by Capt. Blakely to Sir Wm. Armstrong, or any of his champions, to make a 12-inch cannon. This is called forth by an article in the *United Service Magazine* (which is not without a certain official look), in which it is stated that Sir William no longer makes his cannon in the way he certainly did make his experimental and most successful one, and for which Capt. Blakely has a patent.

We hope to see Capt. Blakely's challenge accepted, for the matter is important to all taxpayers. Capt. Younghusband, R.A., in a paper communicated to the Royal Artillery Institution, and published by us in our edition of April 22nd, 1859 (page 261), tells us that Sir Wm. Armstrong first tried solid wrought-iron tubes for his cannon, but afterwards adopted a method which he thus describes:—

"A core, or internal lining for the gun, was formed of cast-steel, to which the requisite strength was given by encircling it with twisted cylinders of wrought-iron, made in a similar manner to gun barrels, and tightly contracted upon the steel core by the usual process of cooling after previous expansion by heat; the parts are then in that state of initial tension which is necessary to bring their entire strength into operation."

It is now said that the initial tension of the outer parts has been abandoned; and Capt. Blakely insists that, if so, efficiency and cheapness have likewise been abandoned. Now, a private individual has a perfect right to adhere to an expensive method of manufacture rather than pay a royalty for the use of a better and cheaper one, but the War Office has not the right thus to spend the money of the nation.

While we had Capt. Blakely's view of the case only before us, we refrained from expressing any opinion; but now that we have seen the reply, we have no hesitation in saying that he has much the best of the argument, and the monopoly of good taste and fairness in using it. Of the absence of the latter quality in the article of the *United Service Magazine* we will

* The Naughton is another instance of some interest, on account of the number of experiments which were tried on her for the Committee. After launching she was kept head to west for some time, this being the position most favourable to the reduction of her original magnetism. When ready for sea, her transverse magnetism was purposely under-compensated, in anticipation of further reduction, and the attraction to the stern, only about 3° or 4° when she was ready for sea, was over-compensated by nearly the same amount by a small bar of iron placed vertically within the skylight forward. The result was, as found by swinging her in the river as she was going to sea, to give a deviation of about 10° W. on a S.W. course. Instead of allowing for the full amount of this error, the Captain steered only half a point west of his course, yet in spite of this precaution he saw both Wicklow lights when he considered himself to be well towards mid-Channel.

give one example. It accuses Capt. Blakely of quoting "newspaper accounts based on no authority." It will hardly be credited that the "newspaper account" quoted is a letter from Sir Wm. Armstrong himself to the *Times*.

ON THE EMPLOYMENT OF AUXILIARY STEAM POWER IN THE MERCANTILE MARINE.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."
Bury, near Gosport, 8th November, 1859.

GENTLEMEN,—With reference to your dissenting note against the quotation from my pamphlet on the "Sail Power of Steam-ships," in the article in your late number on the application of my system to the Royal Navy, I beg to remark that at the time I wrote that pamphlet no remarkable passage had been made by screw steam-ships to or from Australia. I cannot now put my hand on the memorandum which at the time I had collected on the subject; but I remember that the length of passages of several of the screw ships which had made the Australian voyage exceeded that of sailing ships. I also remember being informed that many of the screw ships had sunk considerable sums of money in their voyages. The best proof of the success of anything is the extent of practical use to which it is applied. Why, therefore, do our Australian ship-owners not use steam-power more extensively than they do? And why do they stick so generally to the sailing ships? Furthermore, how was it that those companies who attempted the establishment of steam communication with Australia did not succeed in their spirited enterprise? It is true that the unfortunate Royal Charter had nearly completed the fastest voyage on record, but it has yet to be seen how much of this was due to the *sail power* as well as to the steam. In the article which you refer to in your note, it appears that on one occasion she logged 4,000 miles in forty days; although there was nothing very extraordinary in this run, still it would give her a good shove ahead; and we do not know what other good run she may have had under canvas. In the absence, therefore, of information on this point, I really do not think that the rapidity of the Royal Charter's voyage can be altogether attributable to her steam power, or can be advanced as a conclusive argument against the remarks alluded to. I have yet then to be convinced that except under the circumstances of immensely elastic trade, and, consequently, high freights, or unless with the help of Government subsidy, screw steam-ships can be run with success against sailing ships on the Australian voyage. Even supposing that by the aid of the steam power eight days could be saved in the voyage, which has yet to be proved, the additional expense of keeping the sailing ship and passengers for those eight days falls considerably short of the expense involved in supporting the costly steam-ship.

I do not for one moment wish it to be understood that I entertain the impression that sailing ships are altogether superior to screw steam-ships. It is only with reference to the Australian voyage that I imagine steam-ships have not evidenced the amount of superiority which it was considered they would do before the subject had been put to practical test. In conclusion, with reference to my views of improving the mechanical means for using the sail power, and by thus increasing the capabilities of the sailing ship bringing her up nearer to the capacity of the screw steam-ship for long voyages, I am happy to state that the experience of the past five years has quite confirmed me in these views. Some of the quickest voyages on record, both to and from Australia, India, China, and

elsewhere, have been made by ships fitted on my system, and testimony is borne by the commanders that these voyages have been unquestionably accelerated by the ability which my system afforded them of keeping the amount of the sail power at a more equal rate than could be done on the old method, when the means of making and shortening sail was so laborious and difficult, and thus the speed of the ship maintained more durably, with considerable profit to the voyage. Some commanders have even stated that they consider they have saved ten days in the voyage from Australia. Although I am here alluding to the sailing ships only, consistent with the title of my pamphlet, this improved method of using the sail power applies equally to the screw steam-ships. It must not be overlooked that the ship has to depend much on her sails for long voyages. By all means, then, apply them in the most perfect manner possible to reduce labour and necessity for keeping up a large sailing crew. Bring her as much as possible under mechanical control, both aloft and below, and you perfect her as a machine. My impression, too, is that the steam power is not used so much as it might be in the working of the sails and anchors of the steam-ships. I cannot but believe that by suitable mechanical arrangements the windlass could be worked by steam, and that steam winches might be placed at different parts of the ship, to be used for working the sails. I was witness to this last suggestion being actually carried out. In a trial cruise on board of the Peninsular and Oriental steam-ship *Pera*, Captain Engledue had the topsail halyard taken to the steam winch, and we reefed and unreefed her topsail (fitted of course on my system) with only one man to hold on the slack of the rope! What was done on board the *Pera* could surely be done on board of any ship.

I must really, however, apologise for having intruded so far upon your time.

I remain, yours, &c.,

H. D. P. CUNNINGHAM.

THE ARMSTRONG GUN—A CHALLENGE. TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In the October number of *Colburn's United Service Magazine*, my claim to the original invention of the means whereby Sir W. Armstrong obtains the strength of his cannon is combated on the pretence that Sir William now uses a different method. This question is easily decided by experiment, and perhaps Sir William Armstrong or some of his admirers will consent so to decide it. If so, I will bet five hundred pounds that I get a twelve-inch gun made on the principle said to be rejected which shall be cheaper and better than one made on any other plan.

I shall be exceedingly obliged if you will give publicity to this challenge.

I am, Gentlemen, yours faithfully,

T. A. BLAKELY.

Literature.

The Manufacture of Photogenic or Hydro-Carbon Oils, from Coal and other Bituminous Substances capable of supplying Burning Fluids. By T. ANTISELL, M.D., Professor of Chemistry. New York: D. Appleton and Co. London: 16 Little Britain, and Trübner and Co., 80 Paternoster Row. 1859.

DR. ANTISELL, the author of this volume, is officially charged by the United States Patent Office with the examination of a large class of patented chemical inventions, and is consequently in one of the very best positions conceivable for the compilation of a work like this, particularly as the library of the Patent Office furnishes a ready means of ascertaining the state of the manufac-

ture concerned abroad. Dr. Antisell puts his treatise forth as "the first published monograph on the art of distilling oils from minerals containing bitumen;" and we believe he is correct in this. He has performed his task ably, and produced a valuable history of illuminating oils. The only errors which strike us are a few literal misprints of names, such as Grace Calvert for Crace Calvert, Belford for Bellford, &c.

Examples of Modern Alphabets, Plain and Ornamental. Collected and Engraved by F. DELAMOTTE. London: E. & F. N., 18 Bucklesbury. 1859.

THIS is a companion volume to Mr. Delamotte's "Book of Ornamental Alphabets," which we noticed some time since with much deserved favour. The present volume is not, in our judgment, all that, with the same labour, it might have been made, but it nevertheless contains a great variety of German, Old English, Saxon, Italic, Perspective, Greek, Hebrew, Court-Hand, Engrossing, Tuscan, Riband, Gothic, and Arabesque letters, together with an analysis of the Roman and Old English alphabets (large, small, and numerals) well adapted for the use of draughtsmen, surveyors, masons, decorative painters, lithographers, engravers, carvers, &c.

The Twenty-Sixth Annual Report of the Royal Cornwall Polytechnic Society. 1858. Falmouth: Lake, Market-strand. London: Simpkin and Marshall, and J. Weale.

WE can do nothing better, we think, with this volume, than notice it in this place. The Society seems particularly slow in getting its report before the public, and as it sends us no earlier account of its proceedings, it must of necessity suffer undue obscurity; but it is only fair to say of the "Report," now it is before us, that it is exceedingly well prepared, and deserves to be highly valued by the members of the Society.

On Wages, Trades' Unions, and Strikes. A Lecture delivered to the Operatives in Dunedin Hall, Edinburgh, on Saturday, October 12, 1859. By ADAM BLACK, Esq., M.P. London: Lockwood and Co., Stationers'-Hall-Court, E.C. 1859.

WE put the re-publication of this lecture on record because it deserves the careful attention of all those who need enlightenment on the laws and influences which regulate wages, trades' unions, and strikes.

Proceedings of Societies:

UNITED SERVICE INSTITUTION.

On Friday night COLONEL WILFORD, Assistant Commandant and Chief Instructor of the Government School of Musketry at Hythe, delivered a lecture ON RIFLES AND RIFLE PRACTICE. Lord Elcho, M.P., presided. Colonel Wilford introduced the subject of his lecture by a brief glance at the history and construction of fire-arms. Rifles were mentioned at a target practice at Hamburg, in 1498. They were described as muskets with a grooved inner surface; and from that day to the present rifle-matches had existed in Germany. The rifle was employed by the Jagers, who carried them for the destruction of game that required to be shot by ball. The Austrians did not at first train riflemen, for they found them ready made to their hands among the Jagers. Frederick the Great, in order to meet the Austrian army on equal terms, was obliged to employ riflemen. They remained unknown among English troops until the necessity for them was called forth by the war of American independence. The rifle was necessary to the existence of the backwoodsmen, and when they had the advantage of cover our troops could not stand before them. England was at first obliged to go to Hesse, to Hanover, and to Denmark for riflemen to bring against the Americans; and in 1794 the Government established the 60th battalion of Rifles, which was called the Royal American Regiment. Our first riflemen carried a mallet, with which to hammer down the ball; and the rifleman was so

long in loading that it was necessary the red coats should be near that he might take refuge behind them while he loaded. The Duke of Richmond once said that in the Peninsular war our riflemen were supplied with tight-fitting bullets that would kill, and plenty of small ones that would miss, in order that they might have the pleasure of shooting off. It was at length discovered that the musket supplied to the English infantry was the worst in Europe—the heaviest, the shortest, requiring the largest ball, the greatest charge of power, having the greatest windage, the shortest range, and the least accuracy. It showed what the English soldier must be when he could gain such splendid victories with Brown Bess. The Caffre war was irksome and inglorious, and public attention became attracted to the shortcomings of our fire-arms. General Cathcart was sent out to the Cape with *carte blanche*, and what did he ask for? He said to the Government at home, "Send me out 4,000 Swiss." He wanted soldiers who could hit small objects at long ranges. Brown Bess was clearly unable to bring the war to a close, for it was upon record that one morning 80,000 rounds of ball cartridge were fired, and only 25 Caffres were bagged. George the IV. was very anxious that the cuirass should be adopted in the British army, and that experiments should be tried to show whether it would resist a bullet. A cuirass was accordingly fixed upon a pole and Brown Bess was set to work at it, with the advantage of a "rest." The experiment would have been very satisfactory, only none of the balls could be persuaded to hit the cuirass. At last an officer put a musket to his shoulder, and by great good luck hit the cuirass, when the ball, of course, went through it. He believed that a man might sit in a chair, at 200 yards, and let a man blaze away at him all day with Brown Bess, with one condition only, that the shooter should be bound upon his honour to aim at the mark. A general officer told him that in Spain, being charged with the defence of a breastwork thrown up in a hurry, with a very few soldiers, the order was given to them to fire as rapidly as possible, not in any hope or intention of hitting anybody, but to make the enemy think they were stronger than they actually were. Firing to "make the enemy think!" Contrast this with what took place during the mutiny at Cawnpore. An officer, in command of his company, was attacked by some sowars (irregular native cavalry). He formed his men into two lines, made both kneel, and at the word "Fire!" 69 dragoons fell to the ground like a wall. One man alone escaped the fire, seeing which a soldier came to the front, fired and brought the sowar from his horse at a distance of 300 yards. That was the way to "make an enemy think." Our troops were now all armed with the Enfield rifle, which was the best rifle made which, in similar numbers, had been placed in the hands of any army. By contrast and comparison with Brown Bess it was a weapon of transcendent value and superiority. Upon the beach at Hythe one day, when Sir John Burgoyne was present, a target was put up 8ft. by 6ft., upon which was outlined the figure of a man on horseback. A detachment of 32 men were formed in line at 600 yards distance, who lodged three balls in the horse and two in the man before an officer could get a glass to his eye. Sir John Burgoyne, when he saw this, exclaimed, "No dragoon can stand before you, and no artillery can stand before you unless it is protected." But a new gun required a new man. Men must be taught to shoot as they were trained in any other skilled calling. What was wanted was that all the men in a regiment should be taught to shoot, as all the dragoons in a regiment were taught to ride. In the Government School of Musketry shooting was taught as a drill, without ball at all. The gallant Colonel then entered into a technical description of "aiming drill" and "position drill," and strongly insisted upon the necessity of commencing rifle practice by snapping caps and firing blank cartridge. An important part of a rifleman's training was the ability to judge distances. It was not at first easy, but it could be learnt. The gallant colonel then pro-

ceeded to explain by means of diagrams the line of sight, the line of fire, and the trajectory of the Enfield rifle. The whole difficulty in firing bullets was that they were always travelling through the air at a curve, so that at long ranges it was necessary literally to drop them on a man's head. Armed with the Enfield rifle, no infantry soldiers ever need form a square to resist cavalry, unless surprised. The cavalry might come down upon them, but not a man would escape the aim of their rifles. We did not want the "common soldier" in these days. What was wanted was a taught, educated, and trained man. Some persons said that a range of 400 yards was long enough for the bulk of our troops, but if one soldier had a gun that would kill at 1,000 yards the man whose rifle would only carry 400 yards would not be able to get a single shot at his enemy. The only limit to the range of a gun was the power of the human eye. You might get a longer range by increasing the charge of powder and the weight of the gun, but the rifle then kicked, and where the recoil was great there was an end of accurate shooting. The weight of a gun was also an important consideration, for an infantry soldier required a weapon that he could carry in a 25 miles' march and fight with afterwards. How, then, was a longer range to be obtained? The resistance of the air to any object in motion was in proportion to the magnitude of its surface. In artillery the 68lb. ball, with a charge of 16lb. of powder, was at present the most accurate of aim, but in fire-arms the whole secret of extended range was in narrowing the bore. The Whitworth rifle was constructed on this principle, and at 900 yards' range the bullet from this rifle was going three times as fast as the Enfield. The greater the elevation a rifle required the more skill was wanted to drop the bullet down just where it would hit. It followed that the worse a soldier was the better his gun ought to be, and that the best guns ought to be given to the worst shots. Firing with the Enfield rifle at 800 or 900 yards he often missed the target twice out of five, and sometimes four times out of five, but with the Whitworth rifle he could hit it directly. Mr. Whitworth's rifle possessed the very great advantage of having a low trajectory, and the Enfield rifle the disadvantage of having a very high one; and it might be laid down as a rule in rifle shooting that the certainty of hitting was just in proportion to the lowness of the angle of elevation. [Lord Elcho begged pardon for interrupting the gallant colonel, but should be glad to know the difference in the trajectory of the Whitworth and Enfield rifles.] Colonel Wilford was sorry he could not answer the question. He had heard that the trajectory in the Swiss Federal rifle was very low. Perhaps, it would be more correct to say that the improvement made of late years in the rifle was not so much in the barrel as in the ball. He came there to assure them that accurate shooting could be acquired after a little drill, in a pleasurable manner, if they would only go to work in the same painstaking way as the volunteers who had recently been at Hythe.

INSTITUTION OF CIVIL ENGINEERS.

Nov. 15, 1859.—George P. Bidder, Esq., Vice-President, in the chair. The paper read was "On the Origin, Progress, and Present State of the GOVERNMENT WATER WORKS, TRAFALGAR SQUARE:—with a few facts relating to OTHER WELLS which have been sunk, or bored into the chalk formation," by MR. C. E. ARNOLD, M. INST. C.E. The author commenced by stating that a good supply of water having been required for the fountains in Trafalgar Square, it was determined, in the year 1843, to carry out a plan which had been suggested by Mr. James Easton. This was so framed as to include the water supply for the public offices. The water was to be obtained and raised by engine power, from the springs beneath the London clay. The quantity of water required for condensing the steam of the engine being too great to be taken from the main spring, in full quantity, it was considered expedient to use cooling ponds; and it was thought that a small quantity of water in excess of that required for

the public offices, running continually into the cooling ponds, would keep the water clean, and in a state fit for the purpose of condensation. The basins of the fountains were intended to form the cooling ponds. The water from them was to be taken for the use of the condenser, afterwards to be raised into a cistern, from whence it was to be conveyed to, and be passed through the jets of the fountains, where, meeting with the resistance of the air, it would be partially cooled and returned to the basin, for further circulation. Estimates having been made, it was found that the yearly interest on the cost of erection, added to the cost of working, would be less than the sums hitherto paid annually for the water supply to the public offices, and that, consequently, the plying of the fountains could be effected without cost to the Government. A contract was then made with Messrs. Easton and Amos for the execution of the works, and a piece of ground having been selected in Orange-street, the works were commenced in January, 1844, by sinking the first well to the depth of 174 feet. A cast-iron pipe, 15 inches diameter, was then driven through 30 feet of plastic clay and 10 feet into a stratum of gravel, sand, and stones, being left standing several feet up in the well. Within this another pipe of 7 inches diameter was driven through 35 feet of green coloured sand, and 3 feet into the chalk formation, and the boring was then continued to the total depth of 300 feet from the surface. A considerable quantity of water came from the sand, but a much larger supply was obtained from the chalk. A second well was sunk in the enclosure immediately in front of the National Gallery, to a depth of 168 feet from the surface. A pipe 14 inches diameter was then driven through the plastic clay, and into the gravel, sand, and stones beneath it. Within this a pipe 7 inches diameter was driven through 42 feet of green coloured sand, and 3 feet into the chalk, the boring being continued to the total depth of 383 feet. The springs were found to be stronger than those in the well in Orange-street. A tunnel 6 feet in diameter, and about 400 feet long, was driven to connect the two wells; the bottom of it being about 123 feet below T.H.W.M. A catch well 5 feet 6 inches diameter and 32 feet deep was sunk just outside the engine house. A tunnel was driven from it, passing beneath Castle-street and the National Gallery, to contain the pipes for bringing the water back from the basins of the fountains to the catch well. The paper then proceeded to describe the situation of the different tanks, or reservoirs, in the water tower, and their purpose; and next gave a brief account of the high pressure, condensing steam-engine, on the Cornish principle, for working two sets of pumps, one being capable of raising one hundred gallons of water per minute from the springs to the tank, and the other five hundred and fifty gallons per minute from the catch well into the tank for condensation and for the supply of the fountains. An auxiliary high-pressure, single-acting steam-engine was also provided, to be used when the principal machine needed repair. The works were finished in December, 1844. Their total cost, as completed, amounted to nearly £8,400. The water rose to within 90 feet of the surface (about 48 feet below T.H.W.M.) and was found to be of good quality. When the engine was pumping one hundred and ten gallons of water per minute, it could only lower the water 4 feet in the well. In 1846, a further demand for water having been made, a larger pump was substituted, which was capable of raising three hundred and fifty gallons of water per minute from the springs. In 1849, a second well was sunk in Orange-street, and an engine of 60 H.P., on Woolf's principle was erected. The well was carried to a depth of 176 feet, and a tunnel was driven to connect it with the other wells. A bore pipe was driven through the plastic clay, within which it was intended to drive a smaller pipe through the sand into the chalk, and then to continue the boring as in the other wells. But an accident having occurred in driving the large pipe, which allowed sand to come up the bore hole, and made the water foul, the hole was

stopped with bags of clay, and no further use had been made of it, than as a sump-well to contain the pumps. The accident was accounted for in this way:—In driving the pipe great resistance was offered by the "lugging" of the plastic clay, and considerable percussive force had to be used. In consequence several of the screws which held the joints were shaken out, and the pipe having been improperly driven through the layer of gravel, sand, and stones, into the sand beneath, there was an escape of water through the screw-holes, and sand followed in sufficient quantity to cause inconvenience. The steam-engine worked one double-acting pump for supplying the fountains, and two other pumps for raising water from the springs into the tanks above the building. At an average speed of sixteen strokes per minute, the first could throw six hundred and sixty gallons, and the other two together six hundred gallons per minute. This engine is the one now mainly used. The supply of water from the springs was still found to be abundant. The pumping of six hundred gallons per minute lowered the water from 20 feet to 24 feet, when it remained stationary as long as the engine was kept working. The level of the water did not appear to be gradually lowering, and it was stated that on December 1st, 1858, it rose to within 66 feet of T.H.W.M., being about the same level as it stood in December, 1847. The author thought there could be no doubt that the greater portion of the water was obtained from the chalk. He then referred to the fact of the towns of Brighton, Croydon, Deal, Epsom, Ramsgate, and Woolwich, being all supplied with water from the chalk formation. There was an uncertainty, however, of obtaining a good supply from the chalk, as was illustrated in the case of the well sunk at Messrs. Truman's brewery. In 1857, a greater supply of water being required by the Messrs. Truman, it was determined to extend the works. In the first place the sand and water above the chalk were shut out, then the well was continued to a depth of 300 feet from the top, when it was discontinued, as no water came up the well hole. As the chalk showed indications of water at the depth of 285 feet, the floor of the tunnels was commenced at that level. These tunnels were 5 feet 6 inches high by 4 feet wide; that on the north side was driven to a length of 57 feet, and that on the south side to 48 feet. The quantity of water now obtained did not exceed twelve and a-half gallons per minute. The water of the springs in the sand had been taken by tapping the cylinders at the bottom, instead of, as hitherto, near the top of the sand stratum. A well sunk at Messrs. Combe's brewery, to a depth of about 48 feet into the chalk, produced a supply of seventy gallons per minute. The water stood 20 feet higher in this well than in the Trafalgar-square well, while the water in both wells was in a state of rest.

GEOLOGICAL SOCIETY OF LONDON.

November 2, 1859.—Professor J. Phillips, President, in the chair. William Fryer, Esq., St. John's Wood; Henry Curwen Salmon, Esq., Plymouth; and the Rev. Samuel George Phear, M.A., Emmanuel College, Cambridge, were elected Fellows. Dr. Ferdinand Roemer, Professor of Geology and Palaeontology at the University of Breslau, was elected a foreign member. The following communications were read:—1. "On the passage-beds from the upper Silurian rocks, into the lower Old Red Sandstone, at Ledbury, Herefordshire." By the Rev. W. S. Symonds. 2. "On the so-called mud-volcanos of Turbaco, near Carthagena." By F. Bernal, Esq. In a letter to Sir R. I. Murchison, F.G.S. Turbaco is a village about fifteen miles from Carthagena, at an elevation of about 980 feet above the sea. At a distance of about three miles from the village, and at a rather higher elevation, in the midst of a forest, are some twenty or thirty conical hillocks, about 8 or 10 feet high, each with its little crater or orifice, about two feet in diameter. These are filled with a muddy water; and every two or three minutes a slight noise is heard, a bubbling-up of air or gas takes place, the muddy fluid runs over,

and forms into cakes of blue clay. The water is quite cool, nor is there any present or anterior marks of vestiges of the action of fire or heat. 3. "On the coal-formation at Auckland, New Zealand." By Henry Weeks, Esq. Communicated by the President. 4. "On the geology of the south-east part of Vancouver's Island." By Hillary Banerman, Esq. Communicated by Sir R. I. Murchison, F.G.S.

November 16, 1859.—Professor J. Phillips, President, in the chair. Thomas Harlin, Esq., Fellow of St. Peter's College, Cambridge, civil engineer; Julian Horn Tohn, Esq., C.E., and Associate of King's College, London, 20 Queen Square, Bloomsbury; John Lancaster, Esq., Etruria Hill, Stoke-upon-Trent; the Hon. Robert Mersham, the Mot, Maidstone, Kent; and Arnold Rogers, Esq., F.R.C.S.E., President of the Odontological Society, 16 Hanover square, were elected Fellows. The following communication was read:—"Supplementary researches among the crystalline rocks of the north-west highlands." By Sir R. I. Murchison, V.P.R.S., F.G.S., &c. This communication was offered in corroboration of those views of the Author, already printed in the "Quarterly Journal of the Geological Society" (No. 59), which he first brought systematically before geologists at the Glasgow meeting of the British Association in 1855.

MEETINGS FOR THE ENSUING WEEK.

Mon.—Royal Geographical Society, Evening Meeting. Papers to be read:—I. "San Signals for the use of Travellers," by F. Galton, Esq., F.R.G.S. II. "Latest Accounts of the Central Africa Expedition," from Dr. Livingstone, with illustrations. III. "Notes on Capt. Montgomerie's Map of Kashmir," by W. H. Purdon, Esq., Executive Engineer, Punjab. Tues.—Inst. Civil Engineers, "On Arterial Drainage and Outfalls," by R. E. Grantlun, Esq., M. Inst. C.E., at 8 p.m. Wed.—Society of Arts, "On the Prevention of Accidents in Coal Mines," by Mr. P. H. Holland, at 8 p.m. Geological Society, I. Mr. T. W. Atkinson, "On some copper relics found in a gold-bearing sand in Siberia." II. Mr. W. Hicaphy, "On the extinct volcanoes of Auckland, New Zealand." III. Rev. J. E. Woods, "On some Tertiary beds in South Australia," at 8 p.m.

LUDLUM'S PATENT LIFE-BOAT:

PECULIARLY ADAPTED FOR A SURF-BOAT, GUN-BOAT, SHIP-BOAT, OR PLEASURE-BOAT.

THE following description of this boat, which is now on exhibition at the Crystal Palace, has been submitted to us. All things considered we cannot perhaps do better than insert it just as it stands:—

"It has long been the study of the patentee to more effectually answer the call for help which so often comes from the briny deep. Knowing that in art the grand desideratum is the closest imitation of nature, always perfect in her undistorted offspring, he has seized upon this idea in the construction of his life-boat. In nature the bird has its wings upon its sides, and the fish its fins winged for action as circumstances require. Thus, also, because the floats of Ludlum's life-boat are made adjustable, so that either or both may be fastened by ropes or chains close under the sides of the boat, be extended horizontal with it, or be turned upward quite against or above the gunwales; therefore men within are shielded from shot, seas are not liable to break over it, and the two great defects of life-boats are remedied, viz., liability to capsize and want of self-righting power, in the same boat. The floats are of a conical or egg form in their transverse section, and constructed of cork, or of tin, (more or less,) canisters of zinc, gutta-percha, or for gun-boats of galvanised iron, and covered with wood. They are of such shape as to be well protected by the gunwales, and, with their attachments, may be varied to suit the different style of boats to which they are applied. Should the boat be placed bottom upwards, by a self-acting spring bolt she folds her fins or floats from an extended position, close under her sides, rights herself, and immediately extends them as before. The boat, in case of a self-righting and relieving one, is

LUDLUM'S PATENT LIFE-BOAT.

constructed after the general principles of such boats, with a sufficiency of shear from stem to stern, with high bulk-heads, and with an inner deck, with valves opening to the bottom of the boat. These valves are balanced into place by a lever turning upon a pivot, and are opened downwards by pressure of water from above. The high bulk-heads are made of special service by placing in their bottoms water tanks, opening through faucets into the boat, and filling through tubes from above. Into the bulk-heads above the tanks are inserted valvular air-tight doors, thus creating lockers for the stowage of provisions, instruments, &c. These doors consist of an outer lid, hung and acting by a spring upon an inner lid, covered on its inner side with india-rubber, which is pressed against a rim around the edge of the door. They self-close by an elastic spring. A boat thus 'winged' or 'finned' would long sail a shipwrecked crew upon the open seas, would never swamp or capsize, and is so much like Nature as not to be improved upon. All its fixtures are simple, safe, and self-acting. A surf-boat, with this great length of beam-power, will not capsize; and if its bottom be broken upon rocks, its numerous water-tight compartments within and without will sustain any number in it, and the floats afford a most desirable resting-place for persons in the water. As a gun-boat for Her Majesty's men-of-war it is not easily destroyed by shot, while the buoyancy of the floats make it as fleet as any and much more steady. And for a pleasure-boat it is peculiarly adapted. How often are people drowned while taking an excursion caused by a sudden puff of wind, all getting upon one side, or by carrying too much sail. Now, it is evident the boat is very firm in the water, and that, with her floats spread, twice the canvas of an ordinary boat may also be spread. This boat when on exhibition at the Crystal Palace, in the City of New York, received the unqualified approval of a special committee of sea captains and master boatbuilders, and at the same time there was awarded it the first premium (a gold medal) from the American Institute."

The following is an opinion upon the boat furnished by Captain Hovey, master of the ship Amazon:—

"TO THE EDITORS OF THE 'MECHANICS' MAGAZINE.'"

(GENTLEMEN,—I have thoroughly examined the principles of Ludlum's life-boat, and having spent the past twenty-nine years sailing packet-ships between New York and London, and on one occasion being under Providence the means of saving 185 souls from a sinking steamer during a heavy gale, I am prepared to say I think this invention the greatest improvement of the age. Had I had this boat on the above occasion, in my opinion I could have saved several other lives lost by my boats capsizing.

"I have no further interest in this matter than is felt by yourselves, but hope to see it adopted in this country as more completely supplying the wants of the seas than any other style of boat.

I have the honour to remain, Gentlemen,

"Yours truly,

"H. R. HOVEY,

"Master, ship Amazon, X line.

"London, Nov. 19th, 1859."

The Paris correspondent of the *Times* says that the English steamer *Pilot*, from London, landed three heavy guns, 98 pounders, strengthened at the breech. Also 1,000 shots for these guns, which were immediately forwarded to Paris for artillery experiments in the Polygone at Vincennes.

LOCK'S EMBOSSEING AND STAMPING PRESS, AND STAMP AFFIXER.

THE accompanying illustrations show two ingenious articles lately brought to our notice by Mr. Lock, heraldic engraver, of the Old Jewry, London. The first consists of an apparatus com-

bining both embossing and stamping dies, which are supported by an arm of the ordinary description. In this apparatus the embossing die is fitted in a suitable socket provided with a spring, so that when the pressure of the lever is withdrawn, the die rises clear of the paper. The stamping die or dies are operated upon by the same lever being thrown over from the embossing die. The engraving shows three stamping dies, but any number up to six may be used in an apparatus of suitable size. The second is an apparatus for

affixing postage stamps on to envelopes. In this a box is provided to contain about sixty postage labels, placed singly one above the other, with the gummed side uppermost. The corner of the envelope is first dampened by drawing its surface against a wet sponge, and then it is placed over the stamps, and held there by the operator, who forces down the knob, the pressure of which is sufficient to cause the top stamp to adhere firmly to the envelope. The sponge is kept moist by being connected to a small reservoir partly filled with water. The utility of these articles is evident.

SCOTT'S PATENT STEAM GENERATOR.

MR. G. SCOTT, an engineer of considerable experience, has lately undertaken to do a very important thing for us all—viz., to furnish us with steam boilers or generators which shall be cheaper, smaller, and more easily worked than our present boilers, and at the same time shall combine a very great saving in fuel with almost absolute exemption from explosion. In placing his views before us, with the view of obtaining publicity for them, Mr. Scott has reviewed the defects of the various well-known forms of, and modes of manufacturing boilers, and then dealt with the superheating system, which is growing in favour every day. Superheating the steam by late experiments has, as he says, shown a clear saving of 30 per cent., and is a step in the right direction as far as saving fuel is concerned, but it adds to the complication of the boiler, and leaves the danger of explosion more imminent than before. The old cumbersome boiler is retained with its large quantity of water undergoing the process of evaporation. The steam generated in the boiler passes through a number of pipes placed in the uptake, or that portion of the flue leading to the chimney, where they absorb the heat that would otherwise pass into the atmosphere and be lost, and by this means the steam is raised in temperature, and therefore in elastic force. This, in Mr. Scott's opinion, is beginning at the wrong end; "the object should be to superheat from the beginning," or to use a homely expression, "superheat from the word (Go)!" Allow me to propose the question," he says, "Where is the necessity for such large magazines of power, and of such large quantities of water contained in them? If we look in Nature, and notice the process of evaporation going on, we thereby learn the true mode. Notice how quickly the dew drops are evaporated by the morning sun, or a mist dispelled by the action of his rays. The finely divided particles of water are soon evaporated by the solar fire; or again, notice the evaporating effect of a drying atmosphere, how soon moisture is turned to drought. What is the effect of the hot wind of the desert? To parch, to evaporate, to extract the moisture from everything containing it. Let us remember another fact, viz., the denser a fluid is, the longer it takes to evaporate. Seeing, therefore, that these are natural phenomena, let us copy Nature, knowing the Supreme Architect of the world does all things well. Let us carry out these natural laws of evaporation, and apply them to the generation of a motive power, believing that if properly applied, fuel may be saved, space economized, and explosions rendered next to impossible."

In carrying out the preceding views Mr. Scott forms his generators of lap-welded wrought-iron tubes, one-fourth of an inch thick, formed into a coil as represented in the accompanying engravings. They may consist of any number of coils, one within the other, so as to occupy the whole space in the furnace, thereby increasing the generating surface, without increasing the space occupied by the machine; so also by using one coil, the generating surface may be decreased; or any number of these nests of coils may be enclosed in one casing, and acted on by one furnace, forming a generator of vast power. Tubes of any diameter, capable of being bent, may be used, or even straight tubes may answer the purpose, but he prefers the coil as great strength is combined in its circular surfaces, and it is admirably free from the evils produced by expansion and contraction, and being made in the form of a spiral spring, it is free to expand and contract within itself. The tube being welded, and being only a few inches in diameter, makes an explosion next to impossible. It consists of no joints or couplings to leak or become deranged, but each tube is one continuous length, even to the extent of 200 feet, if necessary. There is no difficulty in carrying a pressure of 300 to 500 lbs. to the square inch, on this small diameter welded-coil generator, with perfect safety. If 50 lbs. pressure be carried on one of the ordinary boilers, 30 feet long, 7 feet diameter plates, three-eighths of an inch thick, all riveted seams, what pressure may be carried on a wrought-

SCOTTS PATENT STEAM GENERATOR.

FIG. 2.

FIG. 4.

iron lap-welded tube, 2 inches in diameter, 100 feet long, and one fourth of an inch thick?—the 100 feet being coiled. Without going into the calculation, it is apparent, he says, to the most uninitiated in the science of mechanics, that the

small tube will be capable of withstanding a greater pressure than the large one, other proportions being equal. It is to be noticed in this generator also, that the safety-valve, and the tube or boiler, are of the same diameter, and not as in

other forms of boilers of very much smaller diameter.

Here, then, is described a form of generator capable of withstanding an immense pressure with safety. And, therefore, the expansive qualities of

very high pressure steam may be taken advantage of in the cylinder of the engine, thereby saving fuel. But it is not in this alone the saving is effected. There is no large body of water for the heat to penetrate and act on as in the case of the old boiler two-thirds full of water. Water and air are together forced into the coil only in such quantities as to generate the amount of steam necessary to work the engine. Water is mixed with common atmospheric air in the proportion of about 30 of air to 1 of water, the water being first heated to about 200 degrees by the exhaust steam from the engine or other means, and the air being heated in tubes up to 400 or 500 degrees. Both air and water are then forced by their respective pumps through finely perforated discs of wire gauze, when they become intimately commingled, and in the form of mist or vapour enter the coil, which is previously heated to a temperature ranging from 800 to 1,000 degrees F., and thus steam is immediately formed of great elastic force. Nor is this all, as the steam passes through each convolution of the coil, it becomes superheated, passing into any suitable reservoir, which is also heated. This reservoir may be composed of any number of tubes, or made of strong boiler iron, and acts as a receptacle for steam, so as to guarantee a steady motion to the engine. It will be perceived that only that amount of water need be used which is required to saturate the air. If the steam be too dry, a little more water can be admitted, which will prevent any injurious effect, such as cutting of valves, &c., the water, in fact, becoming the lubricator.

"Here, then," says Mr. Scott, "we have the mode of generating a highly elastic gas with a small amount of fuel. In the first place the coil is all heating surface, or in other words, all its external surface is exposed to the action of the heat in the furnace, and none of the heat need be lost by radiation by properly clothing the coils and pipes with non-conducting substances. The water and air being introduced at high temperatures, and in a finely divided form, such as mist or vapour, are placed in the best possible state to receive the caloric, and require but a small quantity of fuel to produce sufficient heat in order to obtain a fluid of great elastic force. The heat necessary to thoroughly melt iron is 2,800 deg. F. If a pyrometer be attached to the furnace, it will indicate the amount of heat surrounding the coils, which may be steadily maintained at a temperature of 800 deg. or 1,000 deg., or any other that may be found necessary; by an apparatus which opens and shuts the damper or fire-door, the coils cannot be injured at this temperature, containing as they would at all times, a sufficient quantity of moisture; iron is improved in tenacity up to 600. The tendency to stop up by incrustation does not take place, as a person would be led to suppose, for it is generally found in the old boilers where ebullition is most, precipitation is least, and *vice versa*. Under the peculiar circumstances of ejection above proposed, ebullition is constant all through the coil, the steam perpetually forcing its way to the cylinder. Two years' experience in using limestone water has not shown the least appearance of incrustation. In case of using a number of coils in nests for large power on board a steam-ship, each nest is furnished with a valve opening upward to the steam reservoir—the lower end with a blow-off valve. By opening the blow-off, the valve above closes, thereby cutting off the communication with the other coils. Thus, that nest only is blown off, when if the blow-off is stopped and the feed is opened, so soon as the pressure in that nest is equal to the pressure in the other coils, the valve opens. By this means each nest can be blown off separately without affecting the others. If any derangement of coils takes place, this valve closing cuts off all communication with the others. On board large steamers, using this form of generator, passengers would not be subject to that injurious heat between decks so much complained of, especially in tropical climates, and on board those carrying troops, this generator being so much smaller than the boiler now in use, and being clothed with non-

conducting substances, between decks may become as cool as the external atmosphere."

Homogeneous metal, manufactured under the patent of Mr. Howell, is likely to be extensively used in the manufacture of steam-boilers. The Messrs. James Russell and Sons, of Wednesbury, manufacture tubes of it which can be used in the formation of this new generator with much advantage. This "homo metal" combines the strength of steel with the ductility of copper, making it thereby peculiarly adapted to this form of generator. From experiments made with homogeneous and iron tubes, it has been proved that a tube one-eighth thick of the former will stand as great a pressure as one a quarter of an inch thick of the latter. It does not oxidise or incrustate as rapidly as wrought iron, for which reason it is coming into extensive use in the construction of marine boilers in the navy. In its use many advantages are likely to arise from its application to this form of generator, such as a further saving of fuel, consequent on the tube being one-half the thickness compared with the wrought iron tube; it is, therefore, a better conductor of heat, while its ductility enabling it to be bent and shaped into any form desired is a desideratum. Its lightness, also, is a great advantage in the construction of this form of generator, and there is one in course of manufacture composed of it for public inspection.

The accompanying engravings represent a generator for driving a 50 horse-power engine. Fig. 1 is a vertical longitudinal section; Fig. 2 is a sectional plan through the line X X of Fig. 1. Fig. 3 is a front elevation; and Fig. 4 is a sectional plan passing through Z Z of Fig. 1. A, A, A, A, four coils of pipe in which the steam is generated (3 coils of 2" internal diameter and 1 coil 1 1/2 ditto); a, a, stays to coils; B, steam receiver, to which the coils A, A, A, A are connected; C, steam-pipe; C', safety valve; C², stop valve to steam-pipe; N, pressure gauge; A¹, blow-off cocks to each coil; D, mixing box in which the air and water are mixed and forced through the wire gauge or perforated copper d; D¹, blow-off cock to mixing box; D², check valve to water supply; D³, water supply connected to water pump; e, air supply connected to air pump; E, air check valve; F fire-bars; f, ash pit; G, fire brick lining; H, air space; P, wrought iron casing; P², pipe for blowing off steam receiver; B¹, blow-off cock to same; L, L, fire doors; K, K, K, three openings into flue K¹; H, damper to flue leading to chimney; M, pyrometer.

The following report upon the invention has been made by Mr. J. Finney, of the Poplar Iron Works, at whose establishment we saw the new generator in operation on Saturday last:—

Poplar Iron Works, October 17th, 1859.

Memorandum of experiments with Scott's steam generator fixed at this place to supply steam to an 8 in. cylinder, 12 in. stroke x 90 strokes per minute.

The coil driving this engine commenced work on the 9th August, and worked to the 22nd September and during this 40 days, or about 400 hours, it was often subjected to a temperature which produced on the lower portion of it a blood red heat, and then immediately subjected to cold applications, as the cold air on the outside and cold water pumped inside; after many severe trials of this kind, the tube was taken out, and was found quite perfect and unimpaired, and on cutting up the part which had been red hot, and submitting it to the usual tests, it proved not to have parted with any of its original ductility or strength, and by these means is proved to be as perfect as when it was put up.

During this time it was attended to by a young boy, and was subjected to all the changes and irregularities consequent on unskilled firing; the water used during this time was supplied to the coil cold, as it was pumped from the well on these premises, and proved on evaporation to be the most unfit water for steam purposes, and by analysis is found to contain an unusual quantity of earths, and for this reason its use is discontinued.

The experiments occupied the latter 15 days of the time, and extended over 165 hours, to test the consumption and evaporation. The coke used is gas-coke, and includes all that was used for lighting up in the mornings and waste. The water is the net quantity known to be evaporated.

The coil is 14 in. internal diam. and	47 ft. long
The steam receiver 12 in.	2 ft. high.
The entire capacity for steam	1.92 cub. ft.
The total heating surface	28.86 sup. ft.
The total grate surface	3.69 "
Total water evaporated in 180 hours	31759.5 lbs.—526.5 cub. ft.
Total gas coke used	2893.0 lbs.
Total water evaporated per hour	3.05 cub. ft.
Total coke consumed per hour	23.45 lbs.

This is equal to 9.46 superficial feet of heating surface, and 1.2 super feet of fire grate to evaporate 1 cubic foot of water in an hour, and the result is 11 pounds of water evaporated by 1 lb. of gas coke.

During this trial the steam was used generally at a pressure of 100 lbs. on the square inch, on three occasions at 150 lbs., and on several occasions at 50 lbs.

JOHN FISKE.

Q N B E L L S.

By E. T. LOSEBY.

The following remarks on bells were read by Mr. Loseby, at the Institution of Civil Engineers, on Tuesday, the 8th inst., after the reading of Mr. James' paper on the Westminster bells—a gentleman very competent to speak upon the subject:—

The subject treated in the present paper may be considered under the following heads:—

1st. The qualities which a good bell should possess.

2nd. How to obtain a good bell.

3rd. The causes which occasioned the fracture of the present Westminster bell.

4th. General remarks.

To begin with the first question: The best clock bell, according to my views, may be defined as that which shall weigh the least and yet produce the greatest volume of sound with the lightest blow of the hammer, and that in which the tone produced shall be of the most musical quality and capable of being clearly heard to the greatest distance. These qualities are requisite, in order that the greatest useful effect may be obtained with the smallest and least expensive clock and bell not only in the first cost, but in the constantly recurring expense of winding the clock up and repair of the parts.

These views appear so conclusive that it would have been difficult to imagine how two opinions could exist about them, had not the Westminster bells furnished evidence of views being entertained which are in direct opposition. In those bells the aim appears to have been to increase the thickness to an extent which required an enormously heavy blow to elicit the full tone. In fact, the great weight required for the hammer in proportion to the size of the bell, has been published as one of the best features which those bells contained. It is, therefore, quite time this part of the question were definitely settled.

2nd.—How to obtain a good bell:—The surest way of effecting this object would be to enter into a contract with one of the first bell-founders of this country, binding him to produce a bell entirely on his own responsibility, which shall be first placed in the tower and then be subjected by competent referees to certain specified tests relative to the weight of the hammer required to elicit the full tone, the musical excellence of the tone produced, and the distance to which it is heard, &c.; the bell not to be purchased unless the referees are of opinion that all the conditions have been fulfilled, nor until the bell has been in constant use a full year. An outline of the kind of trial referred to was published and submitted by me to the Board of Works about three years ago, as the test to which the first Westminster bell should be subjected before being purchased, but the suggestion was not acted on by the Board.

The outline of the trial the proposed is equally applicable to any future bells that may be required: but as it may be found in the *Journal of the Society of Arts*, No. 214, and in the *MECHANICS' MAGAZINE*, No. 1737, I need not enter into further details here, and will only mention that the Government did not purchase the bells without going through the form of appointing referees to decide on their merits, but the object was entirely defeated by the designer of the bells being allowed to occupy the position of principal referee, and thus constitute himself the judge who was to pronounce an opinion on the merit of his own work. It is really amusing now to read the caution which I then submitted to the Government, and notice how completely the anticipations have been fulfilled.

3rd.—The causes which occasioned the fracture of the present Westminster bell.—The chief cause of fracture was undoubtedly the great weight and fall given to the hammer, which descended with considerably more force, in proportion to the weight of the bell, than the highest proportion which occurs in the instances that have come under my own observation; and before proceeding further I may as well caution persons against reposing confidence in the reputed weights and measures of bells, clappers, and clock-hammers, unless they have either taken the measures themselves or gleaned the information from a reliable source. Let us take St. Paul's, for instance. Here is a bell situated in the heart of London, and about which one would therefore suppose that every detail would be accurately known and published; but what is the fact? Why, if we consult a parliamentary return, No. 724, session 1847, we find that the fall of St. Paul's hammer is stated to be 10 inches, whereas the actual fall, measured by myself in 1857, proved to be only 3½, or little more than one-third of the reported quantity.

4th.—As St. Paul's is a well-known bell, I may as well employ it to show the comparative force with which the Westminster bell was struck. Taking the fall of St. Paul's hammer, therefore, at the reduced quantity which I found it to have, the force of the blow, compared with the weight of the bell, is still above the average proportion in my list, but it is nevertheless nearly seven times smaller than the proportion of force employed on the Westminster bell, and there is consequently no doubt in my mind about the force given to the hammer being the principal direct cause of fracture in the Westminster bell.

The great thickness of the proportions, which the designer perhaps introduced to carry out his published idea of the best bells being those which require the hardest thumps to make them sound, was no doubt the cause which necessitated the heavy hammer, and therefore the chief indirect cause of fracture, although the designer seems to have considered he was guarding against accident by adding to the thickness; whilst in reality the thickness had a directly opposite tendency, as I will endeavour to illustrate. If, for instance, we take two equal lengths of the same metal, one thick and the other thin, and bend them to an equal distance, we know that the thick length will be more likely to break than the thin one. Well, the circumference of a bell is the given length of metal, and it must be bent to nearly the same degree, whether it be thick or thin, before the full sound can be produced; and, as the hammer which would bend the thin bell will not sufficiently bend the thick one, its weight must be increased until it does so; and, therefore, instead of extra thickness adding to the security of the bell as it is supposed to do, it in reality increases the risk of fracture.

Another likely cause may be traced to the extra dose of tin employed in the composition, which exceeded the usual proportion by about one-fourth of the entire quantity. This would have been found to increase the brittleness considerably in frosty weather, and it may safely be classed amongst the causes of fracture, notwithstanding the mild temperature which prevailed at the time.

If I were to define the proportionate amount of

effect due to each cause of fracture in something of an analytical form, it would be as follows:—

Force of hammer	8.
Extra dose of tin	8.
Uncertain	1.

4th.—General remarks:—It has been assigned, as a probable cause of the fracture, that the hammer occasionally rested upon the bell after the blow, and interfered with its free vibration. It is correct that the india-rubber recoil springs proved so inefficient as to allow the hammer to "chatter" on the bell, and that the tone was therefore impaired, but I cannot regard this circumstance as instrumental in cracking the bell, because in all bells which are swung the clapper invariably rests entirely on the bell after the blow, until the return oscillation.
